Disclaimer of Warranties
and Limitation of Liabilities

The staff of Wang Laboratories, Inc., has taken due care in preparing this manual; however, nothing contained herein modifies or alters in any way the standard terms and conditions of the Wang purchase agreement, lease agreement, or rental agreement by which this equipment was acquired, nor increases in any way Wang's liability to the customer. In no event shall Wang Laboratories, Inc., or its subsidiaries be liable for incidental or consequential damages in connection with or arising from the use of this manual or any programs contained herein.

Warning: This equipment generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instructions manual, may cause interference to radio communications. As temporarily permitted by regulation, it has not been tested for compliance with the limits for Class A computing devices pursuant to Subpart J of Part 15 of FCC Rules, which are designed to provide reasonable protection against such interference. Operation of this equipment in a residential area is likely to cause interference in which case the user at his own expense will be required to take whatever measures may be required to correct the interference.
PREFACE

This manual introduces the Wang 2200MVP system to the user. It describes the features of the basic system and its nominal components: the 2200MVP Central Processing Unit (CPU), an interactive D-type terminal such as the 2236DE Interactive Terminal with business-graphics capabilities, and the diskette drive. Master initializing the system, configuring the system (partition generation), backing up the system platter, executing the user diagnostics, and performing routine maintenance procedures are also discussed.

This manual should be used in conjunction with the following documentation supplied with every system.

- Programming in BASIC — Introduces the beginner to BASIC programming and the utilization of peripherals which are frequently used with the 2200 series of computers.

Additionally, a separate reference manual is provided for each optional peripheral device attached to the system.

CHAPTER 1
INTRODUCTION

1.1 SYSTEM OVERVIEW

Wang's 2200MVP is a versatile, disk-based computer system which concurrently supports multiple users programming in the Wang BASIC-2 language. Up to 12 terminal sites can run up to 16 jobs with the same excellent response-time as a single-user interactive system. The following components constitute a basic 2200MVP system.

- A 2200MVP CPU with 32K to 256K bytes of user memory
- One to twelve Model 2236D-type terminals with business-graphics capabilities*

The 2200MVP also provides multiprogramming (a feature usually available only on larger systems), yet is as easy to use as small single-user systems. The operating system executes several programs concurrently because several users share a single CPU. A terminal can control more than one program, allowing foreground (interactive) and background (noninteractive) processing. Global (reentrant) programs and variables can be shared by users, greatly reducing the memory required to perform multiuser applications. The system overlaps processing and I/O to efficiently use the memory and peripherals that support a variety of applications.

The system is simple to program and operate by using BASIC-2, a variety of powerful system commands, and application software available from Wang and other vendors. Since the user at each terminal may access all system resources directly from the keyboard, no special personnel are required to oversee system operation. This direct access saves programming, job turnaround, and operating time.

The modular design of the system is economical and permits easy expansion and physical relocation of the system's components. Connections between the CPU and each terminal can be either local or remote (RS-232-C/CCITTV.24), thus allowing the system to be adapted to a wide variety of applications and configurations. Each terminal supports a local printer.

Allocation (configuration) of system resources can be redefined as needed by the primary system operator. When security requirements exist, the 2200MVP provides the capability to selectively restrict access to the system's resources.

The features of this system are discussed in greater detail in the Wang BASIC-2 Language Reference Manual (700-4080D).

* The system is capable of supporting 13 terminals via three 2236MXD controllers and one triple controller.
Typical System Configuration

A 2200MVP CPU may be configured with a variety of peripheral devices and options. A typical system might include a 2200MVP CPU with 128K bytes of user memory, three Model 2236D-type terminals for interactive communication with the CPU, a Model 2270A Diskette Drive unit for software loading and system interfacing, a Model 2280-3 Fixed/Removable Disk Drive for data and program storage, and a Model 2263-1 Line Printer for hard copy output. Each unit is attractively designed for easy integration into the office environment. Refer to Figure 1-1 for an illustration of a typical configuration.

System Memory

The 2200MVP utilizes two distinct types of memory: control memory, for system needs, and user memory, for user programs and data. Control memory contains the operating system, BASIC-2 interpreter, and other system data; it is inaccessible to the user or the user's programs and data. User memory contains user programs and data, as well as some system control information. The size of the user memory, which can range from 32K bytes to 256K bytes, determines the "size" of the particular 2200MVP.

User memory is organized into one to four banks. Bank 1 may contain either 32K or 64K bytes of memory, while Banks 2 through 4 must contain 64K bytes each. User memory in each bank is distinct from memory in any other bank, and programs and data in one bank cannot generally access programs and data in another bank. However, the first 5K bytes of available memory in Bank 1 constitute a universal global area; programs stored in this area of memory can be accessed by any other program in the system.

User memory can be divided into as many as 16 separate partitions, each of which can be used for a separate program. A global partition, however, contains programs accessible to several or all users on the system. Up to 12 terminals can concurrently access the memory partitions. Each partition is assigned to either one terminal on the system or to the null terminal during configuration of the system by the operator. However, each partition is controlled by only one terminal at any time, giving each user essentially a stand-alone system with the power and capabilities of a 2200MVP. Each terminal may control more than one partition simultaneously, and ownership of these partitions can be changed during system operation without reconfiguration. Refer to Chapter 3, Section 3.2, for information on partitioning and terminal assignment.

The System Platter

The operating system, BASIC-2 interpreter, system utilities, and other system programs are contained on a system platter. When the system is master initialized, the operating system and interpreter are loaded from the system platter into the control memory. The system platter shipped with each 2200MVP also contains a utility program used to generate, execute, and save system configurations, as well as a variety of hardware diagnostic routines.

NOTE

The system platter must be handled with extreme care, and a backup copy should be made at the earliest opportunity to protect against accidental loss or destruction.
Chapter 3 describes how to load the operating system and the Partition Generator utility from the system platter. Suggested procedures for creating a backup copy of the system platter are also covered in Chapter 3. Chapter 5 discusses the procedure for loading and executing the diagnostic routines from the system platter. Appendix J explains the 2200MVP system utilities.

Interactive Terminals

The 2236D-type terminals enable each user to easily control and communicate with the system. Up to 12 2236D-type terminals can be configured with the 2200MVP CPU. The terminal consists of a 24-line, 80-character-per-line, Cathode Ray Tube (CRT) screen and displays a full 128-character set. Its keyboard contains a 10-key numeric keypad and 34 user-definable Special Function keys. The Model 2236DE Terminal is capable of both box and character graphics and can display bright, blinking, underlined, and reverse video (dark characters on a light background) characters. Special features of the Model 2236DE Terminal also include an audio signal to indicate a variety of error conditions, repeating keys, and the capacity to support a screen dump to its own local printer. The features of the Model 2236DE Terminal are detailed in Chapter 2, Section 2.2.

System Expansion

Because of the 2200MVP's modular design, it is easy to add memory and peripheral devices. The 2200MVP CPU supports up to 256K bytes of user memory. The CPU can be configured with up to 12 terminals, several disk models, high-speed printers (up to 600 lines per minute (lpm)), and industry-compatible nine-track magnetic tape. Appendix B contains a list of peripheral devices which can be added to the system.

The 2200MVP also supports telecommunications. This option allows the system to share information, either locally or remotely, over phone lines and modems, with another Wang system or a host computer.

BASIC-2 Language Features

The 2200MVP, running either the 2200MVP or 2200VP operating system, supports the BASIC-2 language, whose powerful and flexible capabilities provide for a wide range of applications. The BASIC-2 language is compatible with earlier versions of Wang BASIC. Therefore, most Wang software developed for 2200 series systems can be run on a 2200MVP, with minimal changes.

The BASIC-2 language contains instructions for data testing, manipulation, and logical operations at the bit and byte levels, comparable in scope to those of many assembler languages. Many data operation statements can support both numeric and alphanumeric expressions and can operate on all or part of alphanumeric arrays, thereby enhancing the system's data-handling capability. System commands give the operator complete control over system operations from the keyboard and also serve as powerful debugging tools. Statements exist to facilitate common programming tasks such as decision-making, branching, looping, passing data to subroutines, overlaying program modules, and accepting and processing operator-entered data. A variety of instructions are provided for controlling disks and plotters and for formatting output to the printer and CRT displays. Several groups of special-purpose statements perform operations such as code conversion, sorting, matrix arithmetic, and customized
I/O control. Additionally, in the 2200MVP operating system, a number of statements are implemented to support interpartition sharing of programs and variables, temporary control of shared devices by one partition, specification of multiuser system-configuration parameters, and other multiprogramming features.

Numeric operations are carried to 13 digits of accuracy for most operations. The user may specify whether results are to be rounded or truncated at 13 digits. When full precision is not required, numeric data can be packed from eight bytes to as few as one byte. Trigonometric arguments can be specified in degrees, radians, or gradians.

BASIC-2 supports numeric variables and alphanumeric string variables (both scalar and array). The maximum number of elements in one-dimensional arrays is 65,535 and 255 by 255 in two-dimensional arrays. Each alphanumeric array element or alpha-scalar-variable can be from 1 to 124 bytes in length. Alphanumeric arrays can be used in data manipulation statements as scalar variables (element boundaries are ignored), thus providing a convenient technique for manipulating extremely long character strings.

The Operating System

The 2200MVP runs BASIC-2 with the multi-user 2200MVP operating system which supports up to 16 concurrent programs.

The 2200MVP can also operate BASIC-2 under the single-user 2200VP operating system used by the 2200VP and 2200SVP systems. 2200VP BASIC-2, which configures the 2200MVP as a single-user, one partition system, is generally more restrictive than 2200MVP BASIC-2 and therefore, is not normally used with the 2200MVP.

The general instruction set for the 2200MVP is discussed in the Wang BASIC-2 Language Reference Manual. Disk I/O instructions are covered in the Wang BASIC-2 Disk Reference Manual. Instructions used to control all other I/O devices are described in the reference manual for the particular device.

Figure 1-1. Typical 2200MVP Configuration
1.2 ENVIRONMENTAL CONSIDERATIONS

Although the 2200MVP is designed to operate in most office environments, the environment should be designed to encourage optimal system performance. An ideal environment is one in which the temperature and humidity are controlled and airborne contaminants are minimal. The AC power source should be grounded, adequate for present and proposed system needs, regulated, and noise free. The room should have space for future expansion and be easily accessible to operating personnel, yet sufficiently removed from the main traffic flow to permit the system to operate smoothly. A general rule of thumb is: an environment comfortable for the operator will be acceptable for the system. Refer to Appendix C for further information.

1.3 UNPACKING, INSPECTION, AND INSTALLATION

Special factory packing techniques require that the 2200MVP be unpacked, inspected, and installed by a Wang service representative. When the system arrives, call the Wang Customer Engineering Office and request that this service be performed. Failure to follow this procedure voids the warranty.

The Wang service representative will check to see that all equipment has been delivered, inspect each unit for shipping damage, connect each device in the system and perform tests to verify the proper operation of all system components.

If modems and telephone lines are going to be used, this equipment should be installed before the Wang equipment is delivered. The Wang service representative will connect the Wang equipment to the modems. The modem vendor or phone company, however, must connect all modems to the proper transmission lines.
CHAPTER 2
SYSTEM COMPONENTS

2.1 THE CENTRAL PROCESSING UNIT

The 2200MVP Central Processing Unit contains the processor, interpreter, memory, and system logic necessary to resolve and execute programs, perform arithmetic operations, and control the input and output of data. The minimal 2200MVP CPU contains 32K bytes (1K = 1024 bytes) of user memory and nine I/O slots. (Controller boards for peripheral devices are plugged into the I/O slots.) User memory can be expanded to a maximum of 256 bytes.

On systems larger than 64K bytes, data memory is divided into 64K byte banks. The hardware maps the first 8K addresses in each bank onto the first bank. In this shared 8K byte area, 3K bytes of control information is stored. In the remaining 5K bytes, the user may create one or more partitions that have the special property of being accessible to all banks. Partitions created in the remaining 56K bytes of each bank may share data and program text within their bank, but are isolated from partitions in the other three banks.

The CPU and operating system employ many techniques to maintain optimum memory integrity and efficiency. The 2200MVP provides overlapped I/O and program execution, significantly shortening the overall processing time of foreground (interactive) and background (noninteractive) jobs. All programs are stored in a condensed form to save memory. Multistatement lines can also be used to conserve memory, speed program execution, and logically group related statements.

Programmable device selection allows increased flexibility for I/O operations. One user can monopolize the devices allocated to all users during system configuration to secure exclusive access to those devices. (Refer to the Wang BASIC-2 Language Reference Manual for further information.)

System diagnostics automatically verify proper CPU operation whenever the system is master initialized. Additionally, hardware and software errors detected during any system operation are signalled by an audible tone and a code identifying the error and its approximate position. System response to many types of errors can be suppressed if handling errors through program control is preferred. Debugging facilities provide complete program, variable, and subroutine cross-reference listings and allow the programmer to step through the execution of a program one statement at a time, observing variable assignments and program transfers as they occur. The programmer can also interactively edit program lines, immediate mode lines, and input data values both during and after entry.

I/O Controllers

The standard 2200MVP CPU has nine I/O controller slots, each of which holds an I/O controller board used to manage one or more peripheral devices. Some controllers possess front end intelligence, which allows the controller to perform I/O processing and CPU processing concurrently.
The controller for every peripheral device attached to the CPU is identified by a unique device address consisting of three hexadecimal digits. The first digit of the device address is used by the operating system to identify what type of I/O routines are to be used to control the device. The second and third digits of the address represent the hardware address set on the controller, which is used by the system to electronically identify that device when information is to be transmitted to or from it. A printer attached to the CPU is normally addressed 215 and plotters are normally addressed 413 or C13.

The 2236MXD Terminal Processor requires one I/O slot and can support up to four 2236D-type terminals. (Refer to Appendix G for a description of how to set the 2236MXD Terminal Processor device address.) Unlike the device addresses set on most peripheral processors, the physical device address set on the 2236MXD Terminal Processor is not used to access the terminals. Instead, the program address of all CRTs, keyboards and local printers is the same for all terminals on the system. The operating system automatically translates the program addresses into the appropriate physical address for the processor port being utilized. Thus, each program in each partition addresses its terminal and local printer as if they were the only ones on the system. The last two digits of the device address of the CRT are always 05. The device address of the keyboard is always 001. The last two digits of the device address of a local printer (i.e., a printer directly attached to a terminal) are always 04.

If the diskette drive is the only disk unit on the system, the first or left-most drive slot normally has address 310, while the second drive slot has address B10. The procedures for addressing a disk, when more than one drive unit is contained in the system, are discussed in the Wang BASIC-2 Disk Reference Manual. For a more complete discussion of device addresses, refer to the Wang BASIC-2 Language Reference Manual.

Each 2236D-type terminal is connected to a 2236MXD Terminal Processor or a 22C32 Triple Controller which controls data input and output at the terminals. Hard copy printout to a local printer can be created concurrently with CRT displays at each terminal. The terminal processor and triple controller collect keystrokes into lines of text and buffer the CRT and local printer output to contend with the speed discrepancies between the asynchronous line, the CRTs, and local printers. Buffering allows the CPU to be more fully devoted to the execution of programs than would be possible if it had to pause frequently to test the ready status of I/O devices.

Line handling between the CPU and each terminal is asynchronous and full-duplex. Since the 2236D-type terminals and the Model 2236MXD Terminal Processors are RS-232-C/CCITT V.24 compatible, both local and long-distance terminal placement are possible. Local terminals can be placed up to 2,000 feet away from the 2200MVP CPU, while unlimited distance is available for remote terminals using telephone lines and modems.

Any combination of local, extended-local, and remote connection may be used. However, the terminal connected to 2236MXD Port 1 should reside in the same area as the CPU because it acts as the system console for Master Initialization when the system is turned on and for the reporting and correction of system errors. Allowable configurations of the terminals relative to the CPU and 2236MXD processor are as follows.

Local — For distances up to 25 feet (7.6 meters), transmission rates of 19.2K baud are available with a direct four-wire connection using a Wang-supplied cable. (This is the standard configuration.)
Extended Local — For distances from 25 feet (7.6 meters) to 2000 feet (610 meters), optional Wang-supplied cables provide direct extended-local connection at speeds of 19.2K baud. These cables are available in lengths up to 2000 feet (610 meters).

Remote — For distances greater than 2000 feet (610 meters), two asynchronous, full-duplex, RS-232-C compatible modems, operating at the same baud rate, and suitable transmission lines must be used to provide the communications link. One modem is plugged into the terminal and the other is plugged into the terminal processor. The following two types of remote configurations are possible, depending upon the distances involved.

Distances up to 5 miles (8 kilometers) — Short-haul modems using private, voice-grade lines with a four-wire connection between modems may be employed.

Distances exceeding 5 miles (8 kilometers) — Private (dedicated) or switched (dial-up), voice-grade telephone lines provide the connection between telecommunication modems. The modem selected determines whether these lines must be two-wire or four-wire.

Line speeds ranging from a minimum of 300 to a maximum of 19.2K baud may be selected (19.2K baud equals about 1900 characters per second). Baud rates of 300, 600, 1200, 2400, 4800, 9600, and 19,200 are supported. The Model 2236MXD Terminal Processor and the 2236D-type terminal each have a set of switches for setting the transmission speed. Both the Model 2236MXD Terminal Processor and the terminal connected to it must be set at the same baud rate. Special cables for modem connections of Wang equipment are required; they are available in 12-foot (3.7-meter), 25-foot (7.6-meter), and 50-foot (15.2-meter) lengths. Modems must also be set at the same baud rate as the terminal and terminal processor. The procedure for setting the transmission speeds on the Model 2236DE Terminal and 2236MXD Terminal Processor is discussed in Appendix F.

CPU Partitions

The 2200MVP operating system supports multiuser operations utilizing a fixed-partition memory approach. In the first bank of user memory, approximately 3K bytes of memory are required for system overhead. In each subsequent bank, 8K bytes of memory are required. Thus, a 256K-byte 2200MVP contains 229K bytes of memory available for partitions. This memory can be divided into a maximum of 16 partitions. Each partition's size is specified in 256-byte (0.25K-byte) increments, with a minimum partition size of 1.25K bytes required and a maximum size consisting of the remaining available memory in any one bank. However, no partition may be specified which contains memory from more than one bank. Approximately 1K bytes are needed in each partition for overhead, leaving the remaining memory available for user programs and data.

The system configuration (i.e., number and sizes of partitions, the terminals and peripherals attached to each partition, etc.) is defined by a procedure called partition generation. The allocation of system resources (system configuration) can be changed whenever necessary by the primary system operator. Since a number of different system configurations can be generated, named, and stored on the system disk, partition generation can be made similar to loading a program and can even be performed automatically. The process of system configuration and the parameters which can be modified by the user during system configuration (i.e., background/foreground partitions, disabled programming mode, bootstrap programs, etc.) are described in Chapter 3.
Each user has a distinct memory area or partition for program and variable storage. There is, however, only one central processor. The central processor executes the program in each partition sequentially in a round-robin fashion. By bypassing inactive partitions, overlapping I/O with CPU processing, and switching between users frequently, the system assures good response time for each user. This interleaving of the execution of the programs in the system causes the user programs to appear to be executing simultaneously, creating the appearance of a single-user system for each user.

The 2200MVP partitioning scheme imposes some programming constraints on system users because timing considerations of the operating system must be considered. Unbuffered, time-dependent software and associated devices cannot be used with the operating system. For a discussion of programming considerations and BASIC-2 language enhancements for multiprogramming, refer to Chapter 16 of the Wang BASIC-2 Language Reference Manual. If time-dependency is required, the 2200MVP can use the 2200VP operating system; the same hardware, at different times, supports both systems.

The system supports up to 16 partitions, but only 12 terminals at the same time. A single terminal can therefore control more than one partition. Partitions which are currently attached to a terminal (running an interactive job, for example) are said to be running in the foreground. Those partitions which are not currently attached to a terminal (running noninteractive jobs, for example) are said to be running in the background.

A terminal which controls several partitions can be switched from one partition to the next in order to initiate program execution and to permit any necessary user/program interaction. When a program running in a background partition attempts to communicate with a shared terminal but the terminal is attached to another partition, program execution is suspended until the terminal is released by the current partition. A terminal can be released to a specific partition or made available to any waiting partition either by the operator or under program control. For each partition, only the terminal assigned to the partition can list the program in the partition, release the terminal to that partition, or modify the program executing in the partition. A partition assigned to the null terminal, however, can be attached to any terminal upon request. Partitions may be assigned to the null terminal at any time during system operation.

Each partition functions independently of the others in a manner similar to a separate single-user system. However, any partition may declare itself global, thus making its subroutines and specially labeled global variables accessible to other partitions within its bank. Since BASIC-2 program text in a global partition is reentrant, two or more partitions may simultaneously execute the same statement in a shared subroutine. Global variables can be interrogated and modified by several users, providing a convenient mechanism for interpartition communication. (Note that although other partitions can access and modify global variables, they cannot modify global programs.) In many cases, the special features of global partitions also speed throughput and allow several users to concurrently process several related applications at each of the terminal sites. This concurrent processing allows users to share the application programs, thus eliminating the necessity of duplicating those programs. Refer to the Wang BASIC-2 Language Reference Manual for a detailed discussion of global programming capabilities.

Programming and Immediate Mode operations can be inhibited for any partition(s). In the Disabled Programming mode, the operator is kept under BASIC-2 software control, preventing inadvertent or unauthorized use of certain data files and programs. The operator can only load and execute a program called START, which can provide a menu of operations that can be performed and cause other software to be loaded.
2.2 THE MODEL 2236DE INTERACTIVE TERMINAL

The Model 2236DE Terminal is the user's principal means of controlling the system. The terminal's power switch is located in the lower left corner on the back of the terminal. Figure 2-1 shows the location of the two-position power switch. In the UP position (as shown), the interactive terminal's power is on. Turning the power on causes the terminal microprocessor to perform a self-diagnostic to ensure proper functioning of the terminal. After successful completion of the diagnostic, a message is displayed at the top of the screen indicating the current version of the terminal microprogram, communication rate, and communication character format.

Also located on the rear panel are volume controls for the keyboard clicker and audio alarm. Clockwise motion of the volume controls increases the volume of the audio alarm and keyboard clicker. Turning these controls counterclockwise decreases the volume.

![Controls on the Back Panel of the Model 2236DE Terminal](image)

**Figure 2-1. Controls on the Back Panel of the Model 2236DE Terminal**

The terminal connected to Port 1 of the primary 2236MXD Terminal Processor board serves as the primary system console. (Refer to Appendix F for a discussion of how to determine the location of Port 1, if it is not labeled on the terminal processor.) Only the operator at Terminal 1 may master initialize the system and establish the configuration scheme desired. Refer to Chapter 3 for instructions on how to master initialize the system. All system error displays are shown and corrective procedures are taken at Terminal 1. Upon completion of Master Initialization and partition generation, or after the correction of any system error, the primary terminal functions like the other terminals. Only Terminal 1 can function as both the primary (system) console and a standard terminal in the system.

Cathode Ray Tube (CRT)

The terminal's 12-inch (30.4-centimeter) diagonal-measure Cathode Ray Tube (CRT) and typewriter-like keyboard are the principal means of communicating information between the operator and the CPU. Up to 1920 uppercase and lowercase characters can be displayed on the CRT on 24 lines containing 80 characters each. Lines are displayed sequentially on the screen; if more than 24 lines need to be displayed at any time, the new line is displayed at the bottom of the screen, and all previously displayed lines move up one line. Screen brightness and contrast can be adjusted by the operator.
The CRT displays the complete keyboard character set as well as some foreign-language characters, special symbols, and underlined versions of the keyboard characters. In addition, the CRT displays an alternate set of graphic characters which may be used to construct geometric figures on the terminal screen. Special features of the 2236DE Terminal also include a programmable audio signal which can be used to indicate a variety of errors and special conditions, repeating keys, and the capacity to support a screen dump to a local printer.

The Model 2236DE Terminal defines a character display attribute for each position on the CRT display. By using special codes before displaying a character or string of characters, the programmer can cause output to be displayed in bright or normal intensity, blinking or nonblinking, underlined, or in reversed video (dark characters on a light background). Both the regular and alternate character sets may be displayed using one or more of the character display attributes.

Another feature of the 2236DE Terminal is its capacity to produce box graphics. A special BASIC-2 statement, the PRINT BOX statement, can be used to draw any size box beginning at the current cursor location on the screen. Box graphics may be used in a variety of ways when creating charts and diagrams. For example, box graphics increase the readability of a dense display without greatly reducing the capacity of that display.

Refer to the Model 2236DE User Manual for a detailed description of character display attributes and box graphic capabilities. Illustrations of both CRT character sets appear in Appendix D of this manual.

A special display character resembling an underscore is used to indicate the location in the display at which the next character entered will appear. This special character is called the cursor. As characters are entered into the display, the cursor automatically advances to the next character entry position. In Edit mode, the cursor can be positioned to any location in the display where character insertion or deletion will occur. Cursor movement can also be controlled by the programmer. The available cursor control codes are listed in Appendix D.

The screen should be cleaned periodically with a mild soap and water, using a soft cloth. Do not use alcohol or an abrasive compound which could cause damage to the screen and adjacent areas.

---

**WARNING**

Due to the danger of high voltage, do not attempt to remove the cover of your console for any reason. Call your Wang service representative if any maintenance is required.

---

**Terminal Keyboard**

The terminal is designed for users who are already familiar with a standard typewriter keyboard and numeric keypad. The keyboard, illustrated in Figure 2-2, is the operator's means of interactively communicating with and controlling the system. Through the keyboard, the operator can enter data, write programs, perform calculations, and perform command processing. An adjustable keyboard clicker provides audio feedback when a key is sufficiently depressed, and other hardware features (lockout and n-key roll-over) eliminate errors which occur when more than one key is pressed at a time.
The keyboard has two modes of operation, selected by means of a toggle switch labeled A/A and A/a and located in the upper-left corner of the keyboard (see Zone 4). In the A/A mode, all alphabetic characters are produced as uppercase whether shifted or unshifted, and the other keys function in the A/a mode. In A/a mode, the keyboard functions as a standard typewriter, producing uppercase when shifted and lowercase in unshifted operation. Whenever the SHIFT key is depressed, the SHIFT indicator lamp to the left of Zone 1 illuminates. In addition to the standard typewriter-like keyboard for the rapid entry of alphanumeric expressions, the Model 2236DE Terminal contains a 10-key numeric pad, a system-commands key area, and 34 user-definable Special Function keys which can be used to start program or subroutine execution or customized for entry of characters not found on the keyboard. The Special Function keys also access the system-defined Edit Mode functions for changing lines of program text recalled from memory or data currently input and displayed on the CRT.

The RESET key, located to the right of the Mode switch in the upper left-hand corner of the keyboard, immediately stops program execution, listing, and I/O operations; clears the CRT; homes the cursor; signals ready; and returns control to the console user (Console Input mode). RESET is also used during Master Initialization and hardware diagnostic operations. RESET is an undesirable means of terminating execution and generally should not be used to end program execution; HALT/STEP should be used for this purpose.

![Keyboard Diagram](image)

**Figure 2-2. Model 2236DE Keyboard**

The keyboard is divided into four zones as follows.

**Zone 1 — The Alphanumeric Zone**

The alphanumeric zone is designed for rapid entry of alphanumeric and special-character expressions. Similar to a standard typewriter, this zone contains alphanumeric and special characters (e.g., #, $, %), the numeric operators (+, *, /, -, ↑), and the FN, RETURN, and SHIFT keys. The RETURN key is equivalent to the EXEC key on some other Wang keyboard models. The FN key provides Special Function '126 when unshifted and '127 when shifted (see the description of Zone 4 below).
Zone 2 — Program Control Keys
System commands directly control system operations from the keyboard. The command keys provide single-keystroke entry of some of the more commonly used command verbs (e.g., HALT/STEP, RUN, LOAD, CONTINUE, CLEAR, and RETURN). Note that system operations such as CLEAR and RESET, affect only that partition which is currently attached to the terminal from which they are executed.

Zone 3 — The Numeric Zone
The numeric zone is designed like a standard 10-key numeric pad for rapid entry of numeric characters. The numeric keys are grouped here for convenience. Digits may be entered by using the numeric keys in the numeric zone or those in the alpha zone.

Zone 4 — Special Function/Edit Keys
Across the top of the keyboard are 16 Special Function keys. These keys are user programmable. Since each of these keys may be depressed in conjunction with the SHIFT key, a total of 32 Special Function keys is available. The keys are numbered '0'-'15 (lowercase) and '16'-'31 (uppercase). Simultaneously depressing a key numbered '0'-'15 along with SHIFT accesses a key from '16'-'31. A Special Function key must be defined by the user with a DEFFN” statement in the currently loaded program if it is to be used to start program or subroutine execution or display a text string. The Special Function keys are also used during Master Initialization to load the BASIC-2 interpreter and operating system.

The Special Function keys, when used as Edit Mode keys, are described in the following section.

Entering Data into the 2200MVP

The BASIC-2 editor is field-oriented (although, under some conditions, it is possible for a BASIC-2 program to input and validate data character by character). The location of the beginning of the field to be entered may be readily identified by the position of the cursor. As a character is entered, the cursor automatically advances to the next character entry position.

Data entry may be confined to a specific field on the CRT screen. A BASIC-2 program may also make the operator aware of the size of the field by displaying a series of underscores within the field. Attempting to type beyond the end of the specified field sounds the audio alarm. The BACKSPACE key, located to the top right of Zone 1 on the keyboard, is used to move the cursor one position to the left and erase the character in that position. The ERASE key, located to the right of the BACKSPACE key, erases the entire field and positions the cursor at the beginning of the field.

The RETURN key is usually used to terminate the entry of a data item and signal the 2200MVP CPU to process the entered data. The Special Function keys may also be used to terminate an entry, if so defined by the BASIC-2 program. Pressing an undefined Special Function key sounds the audio alarm, but does not otherwise affect system operation.

Pressing the EDIT key places the system in Edit mode, as indicated by a blinking cursor. In Edit mode, the right-most Special Function keys become system-defined Edit keys. The remaining Special Function keys, with the exception of the FN key, are disabled. Edit mode provides the operator with powerful capabilities for editing fields, such as inserting and deleting characters at various positions in the field. These functions are described in Table 2-1.
Text entry and editing are still confined to the field being edited to preserve display integrity. Terminating the entry of the field by pressing RETURN or pressing the EDIT key again causes the system to leave Edit mode and reactivates the user-defined Special Function keys. Edit mode may also be entered under program control.

### Table 2-1. Edit Mode Keys and Their Functions

<table>

CHAPTER 3
MASTER Initializing THE SYSTEM

3.1 MASTER Initialization

Master Initialization is the process of powering up components of the system, loading the operating system and BASIC-2 interpreter, and exercising the CPU to determine if any malfunctions exist. In the 2200MVP, a small bootstrap area of the control memory contains the only resident (hardwired) microcode. The bootstrap area is the only portion of control memory which is functional as soon as the CPU is turned on. Neither user memory nor the remainder of control memory contains any information when the system is first powered up. Before any operations can be performed by the system, the operating system and BASIC-2 interpreter must be loaded from the system platter into the remainder of control memory to manage the processes of interpreting and executing the BASIC text, overseeing variable and program storage in user memory, and controlling I/O.

The 2200MVP can be master initialized only at Terminal 1 (the terminal attached to the primary 2236MXD Terminal Processor at Port 1). For this reason, Terminal 1 should be located at the central system site as near as possible to the CPU and disk drive.

The bootstrap routines are invoked automatically whenever the system is powered up or whenever the operator at Terminal 1 executes the Immediate mode $INIT password command (in order to reconfigure the system or whenever certain CPU malfunctions are detected). The operator need only verify that the system disk is properly mounted and inform the bootstrap routines (via the RESET button and Special Function keys) which disk address to access and which system program to load.

Both user memory and control memory (except for the bootstrap area) are cleared when the system is powered down. Therefore, the system must be master initialized following any power-down operation or whenever the system resources are to be reallocated. In rare instances, it may be necessary to power off and master initialize to recover from an error condition. Always save any desired programs or data residing in memory prior to powering off the system.

Perform the following procedures to master initialize the 2200MVP.

1. Power up the CPU, the system disk, each terminal, and any other device to be used (always power the system up prior to mounting the system platter).

   If the system is already running and Master Initialization is required to reconfigure the system, it is not necessary to power the system components down and power them up again. The Immediate mode form of $INIT, when executed at Terminal 1, causes the system to initiate the bootstrap routines as if the system had just been powered up.

2. Mount the system platter, containing the BASIC-2 interpreter and operating system, as well as a variety of hardware diagnostics and other system programs.
3. Use the RESET and Special Function keys to load the operating system and BASIC-2
interpreter from the system platter into control memory.

Each of these procedures is described in detail in the following paragraphs.

System Power Up

To power up the system, first place the CPU’s Power switch in the ON position. Then turn on
the CRT and printers. As soon as the system warms up (15 seconds), the CRT displays a
self-identification message, such as the following.

2236DE    R01  19200BPS  8 + O  (USA)

where:

2236DE  is the model number.
R01     is the revision number of terminal firmware, preceded by R.
19200BPS is the data rate, followed by BPS.
8 + O   is the number of data bits (7 or 8); E is even parity, O is odd parity, and N is
        no parity.
(USA)    is the version of the keyboard and CRT character set, enclosed in
        parentheses.

Press the RESET key. The following message should then appear on the CRT display of
Terminal 1.

MOUNT SYSTEM PLATTER
PRESS RESET

If the MOUNT SYSTEM PLATTER PRESS RESET message does not occur or if it is incom-
plete, an error has been detected by the bootstrap diagnostics. Master initialize the system
again. If the second attempt fails, refer to Section 5.1 on Master Initialization Error Recovery. If
Master Initialization still cannot be performed, call your Wang service representative.

Mounting the System Platter

The following procedure applies to the Model 2270A-D Diskette Drive and should be followed
when the system platter is first mounted. It is recommended that the system files be copied onto
another disk/diskette and mounted from there at each Master Initialization and that the system
platter be used solely as backup. (Refer to Section 3.5 for backup procedures.)

1. Remove the system platter from its envelope, and check to ensure that the platter
moves freely in the jacket and that the write-protect notch in the diskette jacket is
uncovered (refer to Figure 3-1). When the notch is uncovered, no information can be
written on the diskette, because the diskette is now protected against accidental
destruction (overwriting). Conversely, information can be saved onto a diskette only
when the notch is covered. Figure 3-1 illustrates a diskette showing the write-protect
notch covered (writing on the diskette is permitted) and uncovered (writing on the
diskette is not permitted). The system platter should be uncovered, except when
saving information on it.
Figure 3-1. Diskette Showing the Write-Protect Feature

2. Open the door of the diskette drive by depressing the door latch directly to the left of the door. The door will spring open.

3. Insert the system platter into the drive, paying careful attention to the arrows on the diskette jacket which indicate the proper orientation for insertion (refer to Figure 3-2). If the system platter is not mounted properly, an error will be signalled when the system attempts to read from it. Push the system platter into the drive slot until it catches and holds in the slot.

Figure 3-2. Inserting/Removing a Diskette
CAUTION

Once it catches in the slot, do not attempt to remove the system platter manually; this can result in serious damage to the drive and to the platter. To remove the system platter, close the door until it latches, then press the release button to eject the platter.

4. Close the drive door by sliding it to the left until it locks in place.

5. Once loaded, the system platter can be removed by depressing the drive door latch. The door will spring open, and the system platter will be ejected about halfway out of the drive slot. The system platter should immediately be placed in its protective envelope.

Loading the System Programs

When the system platter is properly mounted, press the RESET key, which is located in the upper-left corner of the keyboard. The following prompt is displayed at Terminal 1.

KEY SF’?

A Special Function key must now be pressed to specify the disk address where the system files are located. (The Special Function keys are arrayed across the top of the keyboard; refer to Chapter 2, Section 2.2.) The following options are available for loading BASIC-2 from the system platter.

- SF Key '00 = Load from disk address D11 (or 310)
- SF Key '01 = Load from disk address D10 (or B10)
- SF Key '02 = Load from disk address D21 (or 320)
- SF Key '03 = Load from disk address D20 (or B20)
- SF Key '04 = Load from disk address D31 (or 330)
- SF Key '05 = Load from disk address D30 (or B30)

The bootstrap also allows the default file name @ @ to be overridden by entering the file name immediately before pressing the Special Function key. The name of the file to load must begin with @ and can be no more than four characters in length. This feature allows more than one operating system to functionally reside on a platter.

Normally, the left-most drive slot in the primary or default diskette unit is assigned address 310, and the second drive slot is assigned address B10. If there is an additional disk unit on the system, the disks on the second drive are usually addressed 320 and B20.

Approximately 15 seconds are required for the BASIC-2 interpreter and operating system to be loaded into control memory from diskette. While they are loading, the following message will appear.

Loading: MVP (Multiuser) BASIC-2 Release X.X

Where X.X will be the number of the release being used.
If the wrong Special Function key is pressed (e.g., if the system platter is mounted at address 310, but the operator presses SF key '01), an error message is displayed of the following form.

*** SYSTEM ERROR (DISK 00XX)***

PRESS RESET

It is generally easy to recover by simply pressing RESET and pressing the correct Special Function key. If RESET fails, turn the system off, wait at least 5 seconds, turn the system on again, and repeat the Master Initialization sequence. If this approach fails, try the Master Initialization error recovery procedures discussed in Section 5.1. If Master Initialization still cannot be completed, call your Wang service representative.

When the operating system is loaded, the system loads and runs the @GENPART program from the system platter. @GENPART will allow the user to interactively create a system configuration or automatically execute any configuration stored on the system platter. @GENPART will also allow other programs resident on the system platter to be loaded into the partitions and executed automatically when the system is configured, with no further operator intervention.

If @GENPART is not on the system platter, the system is configured into a limited 2200MVP system in which Terminal 1, the default disk drive, and any local printer attached to Terminal 1 are ready for limited use and the READY (BASIC-2) message is displayed. The other terminals and system resources can be utilized (i.e., are enabled) only after configuring the system.

### 3.2 PARTITION GENERATION (SYSTEM CONFIGURATION)

Partition generation (system configuration) divides the resources of the 2200MVP system among the various users. This section discusses the use of the @GENPART utility program to create, save, and execute system configurations. @GENPART is supplied with every system on the system platter.

**User-Specified System Configuration Parameters**

The user can specify the following ten parameters when configuring a system.

1. The number of partitions
2. The number of terminals
3. The size of each partition
4. The terminal associated with each partition
5. The programmability of each partition
6. The bootstrap program for each partition
7. The addresses of the peripherals attached to the system
8. The access to peripherals
9. The system message
10. The system reconfiguration password
System Configuration Using @GENPART

The process of Master Initialization*, discussed previously, creates a limited 2200MVP system having a single partition with all of the user memory controlled by Terminal 1. Only Terminal 1, any local printer attached to it, and the system disk drive are operative at this time. No other system devices are available until a configuration is executed. As a part of Master Initialization, the system microcode will automatically load and run the BASIC program file @GENPART from the system platter if such a file exists. (@GENPART is always assumed by the system to be the name of the system configuration program, whether Wang-supplied or user-written.) If @GENPART is not on the system platter, the READY message is displayed at Terminal 1. When @GENPART is first executed, the parameters from the previous configuration (called current) are loaded; a list of previously saved configurations is displayed, along with a prompt inquiring if a different configuration is to be loaded; and the list of @GENPART options is displayed.

The user then proceeds to enter responses to the prompts displayed by each option and uses the Special Function keys to advance from option to option. Refer to the example of this general procedure in Section 3.3.

The standard Wang @GENPART program allows users the following two basic options.

1. Creating configurations to be executed or stored for future use

   If the user is creating a configuration for the first time or wishes to modify a previously defined one, the Special Function keys can be used to load and modify the old configuration or to create a new definition, execute it, and/or store the configuration for future use.

2. Loading and executing previously defined configurations

   If the user wishes to execute a system configuration (previously defined and stored in the configuration file on the system platter) without making modifications, a configuration can be selected from the list of configuration names displayed on the screen and manually executed. (It is also possible to modify the @GENPART utility program so that a specified configuration is loaded and executed automatically when the system is master initialized. This modification is described further in the Customizing @GENPART subsection of this chapter.

@GENPART Options

<td>Displays and allows editing of partition parameters such as memory size, terminal assigned, programmability, and name of bootstrap program. SF'04 does not allow addition of new partitions or deletion of defined ones for an existing configuration.</td>
</tr>
</tbody>
</table>

**Partition Size:** Memory quantity is specified in 256-byte (1/4K) increments.

**Terminal Assignment:** Any terminal number from 0 to 12 is valid. Terminal 0 is the null terminal; a partition assigned to the null terminal is always available to any requesting terminal. Any partition may be assigned to any terminal (a terminal can support several partitions). However, **all partitions must be assigned** to a terminal, even if they are to contain background jobs which never print on the CRT or require keyboard entry. In general, the lowest numbered partition(s) assigned to a terminal should contain the foreground (interactive) job(s) for that terminal. Background jobs should be placed in the higher numbered partitions. Only the terminal to which a partition is assigned can list or modify the program in that partition. Although other partitions can access global program text and modify global variables, it is not possible for other partitions to list or modify the program text in a global partition.
@GENPART Options (continued)

FN -  Help -  Displays @GENPART operating instructions.

### 3.3 GENERATING A SAMPLE CONFIGURATION

The following example illustrates how @GENPART could be used to configure a system. A 2200MVP with 128K bytes of memory, three terminals, and a telecommunications option is to be configured. The configuration (named SAMPLE) will have four partitions. A 16K-byte telecommunications program will be designated for automatic bootstrapping as a background job sharing Terminal 1. Disabled programming will be specified for this partition so it cannot be inadvertently modified. The remaining memory will be divided equally among the other three partitions.
In general, the order of executing options is as follows.

1. SF'08 to load a configuration
2. SF'00 to modify this configuration by adding or deleting partitions
3. SF'04 to create the new partition parameters
4. SF'05 to create the Master Device Table
5. SF'06 to create the broadcast message
6. SF'09 to save the configuration with a name other than "current"
7. SF'15 to execute the configuration
8. SF'10 to delete the configuration

In the example which follows, these options are discussed in the order they would probably be used.

**Load a Configuration (SF'08)**

When @GENPART is first executed, the following display occurs without pressing SF'08.

```
LIST OF STORED CONFIGURATIONS (#PARTITIONS)
current
        (1)
```

CONFIGURATION "current" LOADED. NAME OF CONFIGURATION TO LOAD? ———

The last configuration executed (called "current") is automatically loaded. (To load any other configuration, enter its name, then press RETURN.) Since a completely new configuration is to be created (i.e., the total number of partitions in a previously defined configuration is to be modified), press SF'00 (Clear Partitions).

**Clear Partitions (SF'00)**

The program responds with a display which first requests the number of terminals attached to the system. Prompts requesting the operator to specify the number of partitions in each bank of memory appear next. The amount of available memory in each bank is also calculated and displayed. The figures are then automatically updated after allocation of memory for each partition. Note that in the following display, the system has subtracted the 3K bytes of system overhead from the available memory in Bank 1 and the unavailable 8K bytes from the figure displayed for Bank 2. The display appears as follows.

```
AVAILABLE USER MEMORY = 61.00K 56.00K
REMAINING USER MEMORY = 61.00K 56.00K
NUMBER OF TERMINALS? 3
NUMBER OF PARTITIONS IN BANK 1? 2
NUMBER OF PARTITIONS IN BANK 2? ——
```

In this display, the operator has already specified three terminals attached to the system and two partitions in the first bank. To complete this phase of partition generation, the operator should enter 2 in response to the last prompt, since there will be four partitions in total, and press RETURN. The program automatically invokes option SF'04 (EDIT Partitions) to allow the editing of partition parameters.
EDIT Partitions (SF'04)

This option displays the default parameters for all partitions and initiates a cycle of prompts for altering these parameters. The cycle recurs continuously until another option is selected. The user can modify the parameters for each partition. The display, which is updated each time an item is entered, appears as follows.

<table>
<thead>
<tr>
<th>PARTITION</th>
<th>SIZE (K)</th>
<th>TERMINAL</th>
<th>PROGRAMMABLE</th>
<th>PROGRAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>___</td>
<td>1</td>
<td>Y</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>___</td>
<td>2</td>
<td>Y</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>___</td>
<td>3</td>
<td>Y</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>___</td>
<td>1</td>
<td>Y</td>
<td></td>
</tr>
</tbody>
</table>

EDIT WHICH PARTITION (default = 1)?

In this example, the telecommunications program will be run in Partition 2. Begin by editing the parameters for Partition 2. Enter 2, then press RETURN. An asterisk (*) appears beside the number of the partition whose parameters are being edited, and the following series of prompts is displayed in succession at the bottom of the screen.

PARTITION SIZE (default = X.XXK)?

Any value greater than 1.25K and less than the amount of remaining user memory in the bank is a valid response. (A partition size of 0 is legal whenever the remaining memory is to be divided evenly.) If a partition in Bank 1 is specified such that it resides entirely within the universal global area, a u will appear next to the displayed partition number to indicate this condition. Running the telecommunications program in this partition requires 16K bytes of memory. To allocate 16K bytes of memory to Partition 2, enter 16 and then press RETURN. The following prompt is then displayed.

TERMINAL (default = 2)?

The telecommunications program will be a background job controlled by Terminal 1. To assign Partition 2 to Terminal 1, enter 1 and key RETURN. The following prompt then occurs.

ENABLE PROGRAMMING (Y or N)?

By default, programming is allowed for all partitions. Disabled programming will be specified for Partition 2, however, to prevent inadvertent modification of the telecommunications program. To specify Disabled Programming mode for this partition, enter N, then press RETURN. The name of a program to be automatically loaded into this partition is now requested as follows.

NAME OF PROGRAM TO LOAD?

The name of the telecommunications program which will be run in Partition 2 is TELE-COM. Enter TELE-COM and press RETURN. When the configuration is executed, the telecommunications program TELE-COM will be automatically loaded from the system disk into Partition 2 and run.
At this point, editing of the parameters for Partition 2 is complete. Partitions 1, 3, and 4 require further modification, however. The remaining memory will be divided evenly among the remaining partitions. Press SF'02 (Divide Memory Evenly) and the system responds with the following prompt.

DIVIDE MEMORY EVENLY IN WHICH BANK (default = all)?

Since memory is to be divided evenly in all banks, RETURN is now pressed.

The system returns to the initial EDIT WHICH PARTITION? prompt. Finally, the user must assign Terminal 2 to Partition 4. Enter this value into the table for Partition 4. Upon completion of this operation, the table display appears as follows.

<table>
<thead>
<tr>
<th>PARTITION</th>
<th>SIZE (K)</th>
<th>TERMINAL</th>
<th>PROGRAMMABLE</th>
<th>PROGRAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>45.00</td>
<td>1</td>
<td>Y</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>16.00</td>
<td>1</td>
<td>N</td>
<td>TELE-COM</td>
</tr>
<tr>
<td>3</td>
<td>28.00</td>
<td>3</td>
<td>Y</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>28.00</td>
<td>2</td>
<td>Y</td>
<td></td>
</tr>
</tbody>
</table>

Once all partitions have been edited, SF'05 is used to leave the EDIT Partitions cycle and invoke the EDIT Master Device Table option. Note that it is legal to exit the EDIT Partitions Cycle (SF'04) without answering all prompts.

EDIT Device Table (SF'05)

This option displays the default values in the Master Device Table, which appear on the CRT screen as follows. Note that by default, devices are available to all users.

<table>
<thead>
<tr>
<th>DEVICE</th>
<th>PARTITION</th>
<th>DEVICE</th>
<th>PARTITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>/215</td>
<td>all</td>
<td>17.</td>
</tr>
<tr>
<td>2.</td>
<td>/310</td>
<td>all</td>
<td>18.</td>
</tr>
<tr>
<td>3.</td>
<td>/320</td>
<td>all</td>
<td>19.</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>16.</td>
<td></td>
<td></td>
<td>32.</td>
</tr>
</tbody>
</table>

EDIT WHICH ENTRY (default = 1)?

In this sample configuration, a fourth device (telecommunications controller) is used in addition to the three default devices. The device-address of this controller is /01C. To add this device to the Master Device Table, enter 4 and then press RETURN. An asterisk (*) will appear beside the number 4 in the table. Several prompts are now displayed in succession on the bottom of the screen, and the table is updated each time an item is edited. First, the user is requested to enter the device-address with the following prompt.

DEVICE ADDRESS (default = /000./000 to delete entry)?
Enter /01C and then press RETURN. Another prompt now appears as follows, requesting the user to allocate the device to one or all partitions.

**ALLOCATE DEVICE TO WHICH PARTITION (default = all)?**

Enter 2, then press RETURN to allocate the controller to Partition 2. This cycle will recur to allow the user to edit all entries in the Master Device Table. Since the parameters for all peripherals and partition allocation have been specified, the user can select another Special Function option to exit the EDIT Device Table Cycle.

**Broadcast Message (SF'06)**

When SF'06 is pressed, the following display occurs at the bottom of the CRT display.

**BROADCAST MESSAGE:**

Any message where the number of characters and spaces does not exceed the number of dashes displayed on the CRT is valid. For this example, enter **"* * * THE SYSTEM WILL GO DOWN AT NOON * * *"** and then press RETURN. When the broadcast message has been entered, all partition-generation parameters for the sample configuration have been specified. This configuration can now be saved for later use (SF'09) or executed (SF'15). Pressing SF'09 will allow the operator to save this configuration on disk under a unique name. However, the broadcast message is not saved on disk.

**Save Configuration (SF'09)**

When SF'09 is pressed, the system requests a name for the new configuration by displaying the following prompt.

**CHECK CONFIGURATION TO SAVE. CONFIGURATION NAME?— — — — — — —**

**NOTE**

In order to save a configuration on the system platter, the disk must be write-enabled (i.e., the write-protect notch must be covered). Otherwise, an error will result.

The configuration currently in memory will automatically be saved under the name “current” if the system disk is not write-protected. However, each time a new configuration is executed, its parameters replace the old contents in the “current” file. A configuration should be saved under a unique name so that it can be retrieved for future use. The name to be used for the sample configuration just created is SAMPLE. Enter SAMPLE, then press RETURN. The configuration is saved under the name SAMPLE, and the edited values of the Master Device Table are saved on disk for future use as defaults.
Execute Configuration (SF'15)

Once all parameters of a configuration have been defined, the system configuration can be executed. To execute a configuration, press SF'15. The configuration table will appear near the bottom of the CRT along with the following prompt.

CHECK CONFIGURATION OK TO EXECUTE (Y or N)?

This prompt requests the operator to verify the configuration parameters being executed. If Y (RETURN) is entered, the following prompt is displayed.

RECONFIGURATION PASSWORD? SYSTEM

This password allows the operator at Terminal 1 to reconfigure the system without powering down, while preventing unauthorized reconfiguration. Any alphanumeric string up to eight characters in length is permitted. We will change the reconfiguration password from the default value SYSTEM to some user-defined value. For example, enter SECRET (RETURN). The configuration is executed and the reconfiguration password is now SECRET. In order to reconfigure the system without powering down, $INIT SECRET would be entered and executed to allow the system to invoke the control bootstrap routines (which are usually invoked just after the system is powered up). If N (RETURN) is entered, the system returns to the beginning of the EDIT Partitions Cycle (SF'04).

Delete a Configuration (SF'10)

Since this is only a sample configuration, delete it from the configuration file to save more space for actual configurations. The following prompt will request which configuration to delete.

DELETE WHICH CONFIGURATION?

Enter SAMPLE, then press RETURN, and the configuration will be deleted from the configuration file on the system platter.

Customizing @GENPART

Once they have been initially defined and stored on disk, configuration parameters in a specified system configuration can be passed to the operating system and executed automatically during Master Initialization. REM statements near the beginning of the @GENPART program will tell the user how to modify the program to operate in this manner.

When the Wang utility @GENPART does not meet a user’s needs, it is also possible to create a customized configuration program by using the BASIC-2 statement $INIT. The discussion of $INIT in the Wang BASIC-2 Language Reference Manual presents various methods for producing a customized configuration program.

3.4 USING THE DISK/DISKETTE DRIVE

After the system has been initialized, a disk/diskette drive may be used to store programs or data files. An unused disk/diskette, however, must be formatted before it can be used. Ordinarily, a used disk/diskette is not formatted before storing additional files since formatting destroys any information previously recorded on the diskette. For this reason, disks/diskettes containing packaged programs must never be formatted or scratched.
Formatting a Diskette

As indicated on the permanent label attached to each diskette, a diskette is protected from accidental over-writing when the write-protect notch is uncovered (refer to Figure 3-1). Before programs or data may be written on a diskette, the notch must be covered to disable the write-protect feature. (Adhesive tabs are provided with the diskettes for this purpose.)

To format a diskette, proceed as follows.

1. Remove the diskette from its envelope. Cover the write-protect notch.

2. Properly orient the diskette (as indicated by arrows on the label) before inserting it into the diskette drive (refer to Figure 3-2). Be sure the diskette is firmly seated in the drive, then close the drive latch.

3. To format the diskette, use a pen or pencil to depress the FORMAT button above Drive 1 on the disk control panel. The button must be held in for about one-tenth of a second until the format lamp above the drive slot illuminates. The format lamp remains illuminated throughout the formatting operation, which normally requires 45-50 seconds. At the end of this time, the lamp should extinguish, indicating that the formatting process is complete. If the lamp remains illuminated for longer than 50 seconds, the system has experienced some difficulty in formatting the diskette and is attempting to reformat it. If the diskette cannot be properly formatted, the format lamp will start to blink.

---

**NOTE**

The format button is surrounded by a protective ring to prevent accidental activation of the formatting procedure. This safety feature is necessary because the formatting operation erases any data stored on the diskette.

---

5. If formatting is unsuccessful, a format error (ERR 193) is returned. Generally, format errors result from three causes.

   • The drive latch is not tightly closed.
   • The write-protect notch is not covered.
   • The diskette is defective.

6. Remove the diskette from the drive and proceed to format another.

---

**NOTE**

If a diskette cannot be formatted, it cannot be used for storage and should be discarded.
If the formatting procedure aborts repeatedly with several diskettes, there may be a hardware problem with the diskette drive. Contact your Wang service representative.

**Formatting a Fixed/Removable Disk**

Before a disk may be used for the first time, the disk must be formatted and scratched. *The disk should be formatted only when it is first used* since formatting the disk overwrites all information contained on that disk. There are two ways to format a disk.

1. Implement the BASIC-2 commands.
2. Use the utilities on the operating system.

It is recommended that the system utility be used to prevent accidental formatting of the wrong disk platter. To initiate disk formatting using the system utility, select the appropriate disk and enter LOAD RUN. A menu of utilities on the system will be displayed. Select the Format Disk Platter utility (called @FORMAT), and answer the questions displayed on the screen.

Alternately, you may use the BASIC-2 command, $FORMAT DISK. The general form of the $FORMAT DISK command is as follows.

```
$FORMAT DISK platter
    file #
    { disk address }
```

Some examples of valid syntax follow.

$FORMAT DISK T/D10
$FORMAT DISK T/D11
$FORMAT DISK T/#3

**Defining a Catalog Index**

Before the first program or data file can be stored on a disk/diskette in the Automatic Cataloging mode, the user must create a catalog. The process of creating a catalog is called scratching the disk/diskette because the SCRATCH DISK statement is used to perform the operation. Care must be taken not to scratch a disk/diskette with packaged programs or desired files since a SCRATCH DISK statement overwrites a previous catalog index.

In a SCRATCH DISK statement, the user must specify how many sectors are to be reserved for both the Catalog Index (where the file names are stored), and the Catalog Area (where the contents of the files are actually stored). The Catalog Index always begins at the first sector on a disk/diskette (sector numbering starts with zero) and occupies a number of sequential sectors specified by the user. The Catalog Area begins immediately after the Catalog Index and occupies all sequential sectors up to and including the user-specified last, or ending, sector. The end of the Catalog Area is usually specified as the last available sector on the disk/diskette.

The size of the Catalog Index is defined with the LS parameter in a SCRATCH DISK statement. For example, LS = 10 indicates that 10 sectors are to be reserved for the Catalog Index. If no value is specified, the system assigned (default) value is 24. (The first sector, sector 0, can hold 15 file names, and each subsequent sector can hold 16 file names.)

The last sector in the Catalog Area is specified with the END parameter in a SCRATCH DISK statement. For example, END = 1023 indicates that sector 1023 is the last sector to be used for the catalog area. The user must specify the END parameter.
To scratch a disk/diskette, perform the following steps.

1. Mount a formatted disk/diskette in the drive.
2. Enter a statement such as:

   SCRATCH DISK T/D10, LS = 20, END = 1023

Press the RETURN key. LS = 20 specifies that 20 sectors be reserved for the Catalog Index; END = 1023 specifies that sector 1023 is the last sector to be used by the catalog. The number of sectors allocated for the catalog index and data storage may vary depending on the user’s system and programming requirements. (Refer to the Wang BASIC-2 Disk Reference Manual for further information.)

3. Repeat Steps 1 and 2 for any other disk/diskette that must be scratched. After a disk/diskette is formatted and scratched, it is ready for data and program storage.

**NOTE**

A LIST DC T [/disk address] statement can be used to check the size of the Catalog Index. Entering the statement LIST DC T/D10 after scratching disk D10 in the manner shown above would cause the following to be displayed on the CRT.

<table>
<thead>
<tr>
<th>INDEX SECTORS</th>
<th>END CAT. AREA</th>
<th>CURRENT END</th>
</tr>
</thead>
<tbody>
<tr>
<td>00020</td>
<td>01023</td>
<td>00019</td>
</tr>
</tbody>
</table>

3.5 BACKING UP THE SYSTEM PLATTER

After loading the system programs, the user should first make a backup copy of the system platter. *At least one copy should be made of the entire system platter* on another diskette or on a disk in the fixed/removable disk drive in case the original is accidently damaged or destroyed. The user has a choice between using the BASIC-2 disk commands and the operating system utilities. The BASIC-2 commands and the system utilities provide the flexibility of backing up an entire platter or backing up the platter file by file.

**BASIC-2 Statements**

The following statement will move an entire platter.

MOVE T/xxx, TO T/yyy.

The disk address of the system platter is xxx and yyy is the address of the new disk/diskette on which the copy will be made. This statement copies the entire catalog of the original platter to the destination platter. An example of valid syntax follows.

MOVE T/B10, TO T/310,
To move a platter one file at a time, use the following statement.

MOVE T/xxx, "filename" TO T/yyyy.

This statement causes only the named file to be copied from the Catalog Area of the original platter to the Catalog Area of the destination platter. Two examples of valid syntax follow.

MOVE T/D11, "Bonds" TO T/D10,
MOVE T/310, "@@" TO T/B10,

The BASIC-2 interpreter and operating system are contained in a single file named @@ on the system platter. Other programs on the system platter may be copied, individually, in a similar manner. (Refer to the Wang BASIC-2 Disk Reference Manual for a complete explanation of the MOVE statement.)

Utilities

The system platter contains a variety of system programs. (The file names of these programs begin with the @ (at) sign.) System programs are stored on the disk in Automatic File Catalog mode. (Refer to the Wang BASIC-2 Disk Reference Manual for an explanation of Automatic File Catalog mode.) There are several utilities which will accomplish the task of backing up the system platter.

1. Move System Files (@MOVE)

This utility moves specified system files from one platter to another. The operator must verify each move. Existing files on the destination platter can be overwritten in order to update system programs. To use this utility, select the system platter and press RETURN. Type LOAD RUN @MOVE, RETURN. Another way to access this utility is to type:

SELECT DISK xxx

The address of the system platter is xxx. Press RETURN. Type LOAD RUN RETURN to access the system platter menu. Press the Space Bar to move the cursor to MOVE SYSTEM FILES. Press RUN. The program will provide prompts which require the operator to specify the details of the file transfer. If the system platter is larger than the destination disk, disk error D85 will appear, “Catalog Index Full”. To continue, the operator should mount a new disk platter and create a new catalog.

2. Backup Disk Platter (@BACKUP)

This utility copies the contents of a single disk platter to another platter or to a series of smaller platters. The primary purpose of @BACKUP is to allow 2-, 4-, or 8-megabyte fixed disks to be backed up onto several 1-megabyte diskette platters. This utility moves the entire contents of the origin platter including the Catalog Index, if one is present. To retrieve the contents of the backup platter(s), the @RECOVER utility must be used. (Refer to Appendix K for an explanation of @RECOVER.)

3. Move File (@MOVEFIL)

This utility provides a general file move capability for both system and user files. Specified files are moved from one platter to another; if necessary, a file can span from one output platter to another.
Example of Copying the Entire System Platter onto Diskette

The cursory explanation which follows provides only enough information to create a backup copy of the system platter. The following discussion describes how to back up the system platter by using a Model 2270A Diskette Drive (two disk platters). If the system contains a hard disk drive as well as a diskette drive, the system platter can be copied to the hard disk and then back to a new platter in the diskette drive in order to create a duplicate system diskette. To backup the system platter onto another diskette, perform the following steps.

1. Be sure the write-protect notch on the backup diskette (the new diskette on which the copy is to be made) is covered. Insert the backup platter into the left-most slot of the primary diskette unit (Address 310). Be sure the write-protect notch on the system diskette is uncovered, and insert the system platter into another drive slot.

2. Format the backup platter. Refer to Section 3.4 of this manual for details.

3. Be sure that both the system platter and the new diskette on which the copy is to be made are properly mounted. The system platter and the new diskette may be mounted in separate drive slots in the same diskette unit, or they may be mounted in separate disk units.

4. If BASIC-2 is not currently loaded in the system control memory, load it from the system platter by following the procedure outlined in Section 3.2, "Partition Generation (System Configuration)."

5. Enter a statement of the form:

   MOVE T/xxx, TO T/yyy,

   T/xxx, is the address of the system platter and T/yyy, is the address of the new diskette on which the copy will be made. BE SURE TO SPECIFY THESE ADDRESSES IN THE CORRECT ORDER. For example, assuming the system platter is mounted at Address 310 and the new diskette is mounted at Address B10, the following statement would be entered.

   MOVE T /310, TO T /B10,

   The trailing comma (e.g., T/B10,) is required by BASIC-2 syntax. Failure to specify the comma yields ERR S13. For a detailed explanation of the errors which can occur during BASIC-2 operation, consult Appendix A of the BASIC-2 Language Reference Manual.
6. When the MOVE statement has been correctly entered, press RETURN (EXEC). The CRT colon will disappear while the MOVE operation is in progress. When the colon reappears, the Move is complete. The new copy must now be verified.

7. The new platter should be verified immediately following the MOVE operation to ensure that the system programs have been correctly copied to it. To verify the platter, a statement of the following form is used.

   VERIFY T /yyy,

   The device address of the platter to be verified is /yyy. For example, if the system platter has just been copied to a diskette at Address B10, the following statement would be used to verify the new copy.

   VERIFY T /B10,

   When the VERIFY operation is completed successfully, remove and carefully label the new copy.

   If the VERIFY operation reports an error, repeat the MOVE operation and verify the platter again. If the VERIFY operation still indicates an error, use a new platter for the copy. If the VERIFY operation continually detects an error on the new platter, contact your Wang service representative.
CHAPTER 4
OPERATING THE 2200MVP

4.1 INTRODUCTION

The 2200MVP is a versatile system which can be used as both a programmable data processor and a convenient and powerful calculator using the Wang BASIC-2 language. Wang BASIC-2 is an interactive programming language which uses many English words (such as PRINT, READ, and STOP). Although such words are given a special and clearly-defined meaning when used in a BASIC-2 program, their usage and meaning is similar to that of commonly-used English. Detailed information about the Wang BASIC-2 instruction set is presented in the Wang BASIC-2 Language Reference Manual. Programming techniques are discussed in detail in Programming in BASIC.

This chapter introduces the user to the operation of the 2200MVP. It includes general instructions for running preprogrammed software modules and provides information on using the 2200MVP workstation as a calculator. Additionally, this chapter presents a sample BASIC-2 program, along with an explanation of the program itself and the procedures for entering, running, and saving the program.

4.2 RUNNING SOFTWARE PACKAGES

Preprogrammed software packages may be run easily on the 2200MVP. First, insert the program diskette in the Model 2270A-20 Diskette Drive. Most Wang-developed software packages contain starting modules named START, although some have starting modules with other names. Check the manual supplied with your software package for the required module name.

Loading the Starting Module

When software packages contain the file START, enter the following command.

SELECT DISK xxx

The diskette containing the software package is xxx. When the following statement is entered, it will clear memory, load the starting module, and begin program execution.

LOAD RUN (RETURN)

If the software package does not contain a program module named START, enter the following commands.

CLEAR (RETURN)
LOAD RUN [/disk address]. “xxxxx” (RETURN)

The name of the starting module is “xxxxx”.

4-1
Entering Data

During program execution, operator prompts usually appear on the CRT. The following facts should be remembered when responding to these prompts.

- In general, a displayed question mark indicates that the system expects a keyboard entry.

- If a numeric value is requested, the system permits a maximum of 13 digits, a decimal point, a sign, and a signed 2-digit exponent to be entered. (The program itself may impose more restrictive limits on a response.) The sign of the value must precede the digits; the letter E is used to mark the beginning of the exponent. The following are examples of system-acceptable numeric entries.

  25.15
  - 79.5
  4.56E4
  +23.2437E-12

- If an alphanumeric response is requested, the system accepts any keyboard characters except for some sequences containing commas and double quotes. (Refer to the INPUT statement in the Wang BASIC-2 Language Reference Manual.) Most software packages remove the restrictions imposed by the INPUT statement by using the KEYIN statement.

- The Edit mode keys may be used to correct a response before entering a response to a prompt (refer to Section 2.2).

- When a response has been typed in and appears on the display in the desired form, press the RETURN key to enter the response and terminate the keyboard entry.

- After a response is entered, the system may signal an error condition with a message in the form of ERR Yxx, where Y represents a letter prefix of the error class and xx represents an error number (refer to Appendix E for a discussion of system execution error messages). The question mark will reappear on the screen; this indicates that the entered response was not acceptable to the system. To continue, check the form of the response and enter another.

4.3 USING THE 2200MVP IN IMMEDIATE MODE

The 2200MVP can perform as a calculator when a BASIC-2 statement is entered without a preceding line number. When such a statement is entered and executed, the 2200MVP is in Immediate mode. To perform quick calculations, a user can enter unnumbered, single, or multiple statement lines in Immediate mode, using the PRINT statement to display the results. If the system detects no syntax errors, it executes an Immediate mode statement immediately when the operator presses the RETURN key, as in the following example.

:PRINT 25 + 273 (RETURN)
:298
In this case, when the operator presses the RETURN key, the line is immediately executed, the expression \( 25 + 273 \) is evaluated, and the result is displayed. The line is not saved in memory because it was not preceded by a line number when entered.

Multiple statement lines (individual statements separated by colons) are acceptable in the Immediate mode, such as in the following example.

`:PRINT 3+8: PRINT 15/9: PRINT 144/4.2`

Upon execution, the following is displayed on the screen.

```
11
1.666666666667
34.28571428571
```

The Special Function keys along the top of the 2236DE Terminal can be used to edit an Immediate mode statement. To activate the editing capabilities of these keys, first press the EDIT key, located in the top right corner of the terminal keyboard. For example, pressing the EDIT key then pressing the RECALL key will cause the most recently entered Immediate mode statement to appear on the screen where it can be edited and re-executed. The capabilities of these keys are explained in Table 2-1.

**Arithmetic Operations**

The 2200MVP can operate on numeric quantities as large as \( 10^{100} \) and as close to zero as \( 10^{-99} \). The quantities may be positive or negative. Quantities within this range can be represented by a maximum of 13 digits, a decimal point and sign, and a two-digit positive or negative integer exponent. The letter E in a quantity means times ten raised to the power of.

The arithmetic symbols, or operators, of BASIC-2 are the following.

+ addition
- subtraction
* multiplication
/ division (5/4 reads 5 divided by 4)
† exponentiation (5 † 4 reads 5 raised to the 4th power)

Any number of variables and constants in an expression can be linked together by arithmetic symbols. Some simple expressions, using arithmetic symbols, are underlined as follows.

```
PRINT 12/7
PRINT 23*11.0000*32.1*4
PRINT 63/22.5E23
PRINT 4#23
```

Expressions using the same arithmetic operators are evaluated left to right. For expressions with mixed arithmetic operators, the following priorities of evaluation are observed.

All exponentiation (†) is performed left to right.
All multiplication and division is performed left to right.
All addition and subtraction is performed left to right.
Not all combinations of constants and variables connected by arithmetic operators are valid expressions. In order for an expression to be valid, it must be capable of being evaluated in the stipulated sequence. At each state of evaluation, the operation to be performed must be defined for the given values, and must yield a valid numeric quantity. For example, the expressions in Table 4-1 are invalid for the reasons shown.

### Table 4-1. Invalid Arithmetic Expressions

<table>
<thead>
<tr>
<th>Invalid Expression</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>(3.4E26 4)/9.7E17</td>
<td>3.4E26 4 yields an invalid numeric quantity of $10^{100}$</td>
</tr>
<tr>
<td>17/((4*5)-20)</td>
<td>After evaluating ((4*5)-20), the system attempts to divide 17 by 0, an undefined operation.</td>
</tr>
<tr>
<td>(-3) ↑ 3.5</td>
<td>The exponentiation (↑) operation is undefined for non-real results.</td>
</tr>
</tbody>
</table>

If the result of evaluating an expression or a portion of an expression yields a quantity $Q$ in the following range, the value of $Q$ is zero.

$$-10^{-99} \leq Q \leq 10^{-99}$$

### BASIC-2 Functions

A BASIC-2 function is a special type of instruction which accepts a given value as an argument and returns a unique value as a result. The result of a function can be displayed in Immediate mode if the function is included in a PRINT statement. PRINT SQR(55), for instance, prints the square root of 55.

Some BASIC-2 functions that may be useful in Immediate mode are as follows.

<table>
<thead>
<tr>
<th>Function</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCCOS</td>
<td>Returns the arccosine of an expression.</td>
</tr>
<tr>
<td>ARCSIN</td>
<td>Returns the arcsine of an expression.</td>
</tr>
<tr>
<td>ARCTAN (or ATN)</td>
<td>Returns the arctangent of an expression.</td>
</tr>
<tr>
<td>EXP</td>
<td>Finds the value of e raised to the value of the expression.</td>
</tr>
<tr>
<td>LOG</td>
<td>Returns the natural logarithm of an expression.</td>
</tr>
<tr>
<td>SIN</td>
<td>Returns the sine of an expression.</td>
</tr>
<tr>
<td>SQR</td>
<td>Finds the square root of an expression.</td>
</tr>
<tr>
<td>TAN</td>
<td>Returns the tangent of an expression.</td>
</tr>
</tbody>
</table>
Other BASIC-2 functions and keywords are explained in detail in the Wang BASIC-2 Language Reference Manual.

Numeric Variables

When used in Immediate mode, the 2200MVP can assign values to variables and perform operations on those variables. A numeric variable in BASIC is designated by a letter of the alphabet A-Z or a letter followed by a single digit such as A0, A1, A2-A9, B0, B1-B9, C0, C1-Z7, Z8, and Z9. The letters in variable designations must be uppercase. Variables such as A and A0 are distinct. There are 286 numeric variables available for use in BASIC-2. A numeric variable may be assigned any legal numeric value.

Variables retain their values until they are explicitly cleared from memory or assigned new values. The commands CLEAR, RUN, and LOAD RUN are some of the commands that cause variables to be cleared from memory.

Care should be taken when assigning variables in Immediate mode since Immediate mode commands can change the values stored in variables created by a program. Immediate mode operations involving variables should be performed only at times when it is known that disturbing the values stored in the program-created variables will cause no harm. While running a program, it is best to refrain from performing Immediate mode calculations that involve variables, unless the author of the program has specifically documented that Immediate mode operations will not adversely affect the operation of his program.

For further information on BASIC-2 variables, refer to the Wang BASIC-2 Language Reference Manual or Programming in BASIC.

4.4 A SAMPLE PROGRAM

It is not difficult to program using BASIC-2 on the 2200MVP. The simple syntactical rules and most frequently used commands can be learned very quickly from reading Programming in BASIC. With this knowledge, even a beginner can write simple, functional programs. Further reading and practice will provide facility with the more advanced BASIC-2 commands and features. The Wang BASIC-2 Language Reference Manual, the prime source of the wide variety of commands, functions, and statements to which the 2200MVP will respond, discusses the many BASIC-2 programming features which can make programs more powerful and efficient.

This section discusses how to enter and run a simple program, list it on the CRT screen and printer, save it on disk, retrieve it from disk and modify it, and resave it on disk.

An Adding Machine Program

A program is a set of instructions enabling a computer to receive data, manipulate it, and return it to the operator in a desired form. The following program has been written to make the system function like a simple calculator: when the program is executing, the user will enter two numbers on the keyboard and indicate the operation he wishes to perform upon them. The system will display the answer on the CRT screen.

A program line is entered by typing in a line number, followed by one or more BASIC-2 statements and their operands. Each line is terminated by pressing the RETURN key. When the RETURN key is pressed, the entire line is saved in memory.
It is customary to number program lines in multiples of 10; this enables a programmer to insert new lines between already existing lines by assigning the new line an intermediate statement number. When the operator enters such a line on the keyboard, the computer will place it in its proper place in the program. The computer normally will execute these statements in sequential order, though several BASIC-2 statements allow the operator to change the order of execution.

Type in the following program on the keyboard, pressing the RETURN key after each line is entered.

```
10 DIM A$:1
20 INPUT "WHAT TYPE OF OPERATION (+,-,X,/) DO YOU WANT TO PERFORM", A$
30 INPUT "ENTER FIRST NUMBER", A
40 PRINT A; A$; " ";
50 INPUT B
60 IF A$ = "+" THEN GOTO 170
70 IF A$ = "-" THEN GOTO 180
80 IF A$ = "*" THEN GOTO 190
90 IF A$ = "/" THEN GOTO 200
100 GOTO 20
110 PRINT A; A$; B; "\nEQUALS\n"; C
120 INPUT "DO YOU WANT ANOTHER OPERATION", B$
130 IF STR(B$,1,1)="Y" THEN 20
140 IF STR(B$,1,1)="N" THEN 160
150 GOTO 120
160 END
170 REM ADDITION: C=A+B: GOTO 110
180 REM SUBTRACTION: C=A-B: GOTO 110
190 REM MULTIPLICATION: C=A*B: GOTO 110
200 REM DIVISION: IF B<0 THEN 220
210 PRINT "DIVISION BY ZERO IS AN ILLEGAL OPERATION. START AGAIN PLEASE":
    GOTO 20
220 C=A/B: GOTO 110
```

Listing the Program

To review the program entered in memory, enter the LIST command.

```
LIST
```

This statement will list the entire program on the CRT. The LIST S command lists the program a screen at a time; the operator must press the RETURN key when ready to review each subsequent screen. LIST [line number] lists the specified line only; LIST 10, for example, lists only Line 10.

To obtain a hard copy listing of the program on a printer, turn on and manually select the printer (press its SELECT switch). (When the printer is selected, its SELECT switch indicator lamp is illuminated.) Then, enter the following statement from the keyboard to select the printer for listing.

4-6
SELECT LIST 215

This statement changes the default output address for the I/O class parameter LIST from the primary address 005 (the CRT) to the address 215 (the system printer). Next, enter LIST and press the RETURN key. Program listings formerly displayed on the CRT are now listed on the printer. To again obtain program listings on the CRT, enter the following statement.

SELECT LIST 005

Next, enter LIST and press the RETURN key. If a local printer is attached to the rear of the 2236D-type interactive terminal, it may be accessed at address 204. Further discussion of the SELECT statement and its various parameters can be found in the Wang BASIC-2 Language Reference Manual and in the individual printer manuals.

Running the Program

Once the program is saved in memory, it can be executed by pressing the RUN key. Note that the program text is saved in memory each time that RETURN is pressed. When the RUN key is pressed, followed by the RETURN key, the screen will display the following prompt.

WHAT TYPE OF OPERATION (+,-,X,/) DO YOU WANT TO PERFORM?

As an example, enter +. The screen will display the following.

ENTER FIRST NUMBER?

Enter 25. The following will be displayed.

25 + ?

Enter 75. The following appears on the screen.

25 + 75 EQUALS 100
DO YOU WANT ANOTHER OPERATION?

Enter YES. The program will once again ask, WHAT TYPE OF OPERATION (+,-,X,/) DO YOU WANT TO PERFORM?

The program has been designed to recognize an attempt to divide by zero. Enter /. When the screen displays ENTER FIRST NUMBER?, type in 100. The following appears on the screen.

100 / ?

Enter 0. The screen will display the following.

DIVISION BY ZERO IS AN ILLEGAL OPERATION. START AGAIN PLEASE.
WHAT TYPE OF OPERATION (+,-,X,/) DO YOU WANT TO PERFORM?

The program will continue processing until the user enters NO or N to the question, DO YOU WANT ANOTHER OPERATION?
Explanation of the Program

The adding machine program instructs the computer how and where to store information entered by the operator or produced by processing, sends prompts to the operator on the CRT screen, accepts operator input from the keyboard, processes entered data according to a defined formula, and displays results on the screen. The following section examines the program line by line and discusses the use and purpose of each BASIC-2 command.

Line 10:

10 DIM A$1

The DIM statement in Line 10 is a dimension statement, limiting the length of the information which can be stored in variable A$. The only reason the program includes this statement is to guarantee that, if an operator entered an inappropriate response such as + + + + + + + + to the question WHAT TYPE OF OPERATION (+,-,X,/) DO YOU WANT TO PERFORM?, the adding machine program would not generate a prompt on the screen such as the following.

44 + + + + + + + ?

Because of the dimension statement, the system will cut off the six extra plus signs and store a variable of one character only in length. As a result, the screen shows the following.

44 + ?

There are many other uses of the DIM statement. Refer to Chapter 8 of Programming in BASIC and Chapters 1 and 11 of the Wang BASIC-2 Language Reference Manual for more information on the DIM statement.

Lines 20 and 30:

20 INPUT "WHAT TYPE OF OPERATION (+,-,X,/) DO YOU WANT TO PERFORM",A$
30 INPUT "ENTER FIRST NUMBER",A

The INPUT statements in Lines 20 and 30 are the computer's way of receiving information from an operator. The computer stores the information entered by the operator in variables, such as A$ and A in this program. A$ is called an alphanumeric variable. Alphanumeric variable names can be distinguished from numeric variable names by the presence of a dollar sign ($) immediately following the variable name. Alphanumeric variables may contain any kind of character: letters, digits, or special characters, but may not be used in mathematical computations, because they do not necessarily contain numbers. A$ in this program is used to store the character +, -, X, or /. (Refer to Chapter 1 of the Wang BASIC-2 Language Reference Manual for more information on variables.)

The phrase in quotes is called a literal; here it is used as a prompt to the operator to enter the first number of the arithmetical operation. The INPUT statement automatically displays a question mark following the prompt. BASIC-2 does not require the literal in the INPUT statement. If the literal is omitted, the INPUT statement simply displays a question mark. A lone question mark is of little use to an operator who does not know the program, so it is a good idea to always provide prompts for the operator. The literal in the INPUT statement is one means of providing prompts.

Lines 40 and 50:

40 PRINT A; A$; " "
50 INPUT B

The PRINT statement causes values and literals to appear on the CRT screen. Additionally, its punctuation can determine the spacing of the printed material. A comma will cause elements to be displayed in zones, each 16 characters wide. This is ideal for charts, where figures must be arranged in columns and rows, but it is not convenient for this program. A semicolon is used in this program, because it causes no additional spaces to be placed between printed elements.

In Line 40, the PRINT statement instructs the computer to display the current value of variables A and A$. As in the INPUT statement, literals (those characters and phrases contained in quotation marks) are displayed on the screen as written in the program line, even if the literal is a blank space, as in Line 40.

Refer to Chapter 3 of Programming in BASIC and Chapter 11 of the Wang BASIC-2 Language Reference Manual for more information on the PRINT statement.

The INPUT statement in Line 50, an example of an INPUT statement not containing a literal, causes the question mark to appear on the screen. For example, when the program is run as in the Running the Program section above, 25 + ? appears. The value of A is 25, and + is the value of A$. The space after the addition sign results from the coding of the literal space, " ", in Line 40. The question mark results from the INPUT statement and is placed immediately after the literal space due to the semicolon in Line 40.

Lines 60-90:

60 IF A$ = " + " THEN GOTO 170
70 IF A$ = " - " THEN GOTO 200
80 IF A$ = " X " THEN GOTO 210
90 IF A$ = " / " THEN GOTO 220

It is not always desirable to have the computer execute program instructions in statement number sequence. Two ways of altering the sequence of program execution are demonstrated in the adding machine program. Lines 60, 70, 80, and 90 use the IF ... THEN statement to cause execution to be diverted to the portion of the program which handles the appropriate arithmetic operation specified in variable A$. Another statement, the GOTO statement, is used later in the program to redirect the order of program execution.

Lines 60, 70, 80, and 90 test the value entered for the alphanumeric variable, A$, that is, they determine what operation the user wishes to perform on the values assigned to variables A and B. This test enables the the computer to branch to a special routine for each operation. In the special routine, the computer can compute the solution of the operation, store it in a variable, and return it to be processed in Line 110 for display upon the screen. When A$ has a value of +, the program will go to the addition routine at Line 170. When A$ has a value of -, the program will go to the subtraction routine at Line 180. When A$ has a value of X, the program will go to the multiplication routine at Line 190. When A$ has a value of /, the program will go to the division routine at Line 200.
Refer to Chapter 3 of *Programming in BASIC* and Chapter 11 of the Wang *BASIC-2 Language Reference Manual* for more information on the GOTO statement.

Line 100:

100 GOTO 20

If the user enters any value other than +, -, X, or / for A$, the computer will fall through statements 60, 70, 80, and 90 to Line 100, where the GOTO statement will send the program back to Line 20. This GOTO statement ensures that an operational symbol has been entered.

Lines 170-190:

170 REM ADDITION: C = A + B: GOTO 110
180 REM SUBTRACTION: C = A - B: GOTO 110
190 REM MULTIPLICATION: C = A * B: GOTO 110

These three lines are examples of multistatement lines. In each, three short statements are grouped together, separated by colons. Short statements are grouped together to keep the program from growing too large and to aid in program clarity. The purpose of the REM statement is to document the program. Here, REM ADDITION labels the portion of the program which computes addition problems. A REM statement is a nonexecutable statement ignored by the computer when the program is run, but displayed whenever a program is listed.

Refer to Chapter 3 of *Programming in BASIC* and Chapter 11 of the Wang *BASIC-2 Language Reference Manual* for more information on the REM statement.

Lines 200-220:

200 REM DIVISION: IF B < > 0 THEN 220
210 PRINT "DIVISION BY ZERO IS AN ILLEGAL OPERATION. START AGAIN PLEASE": GOTO 20
220 C = A / B: GOTO 110

The division routine is given three lines to ensure that an operator does not enter zero as a divisor. If Lines 200 and 210 did not exist, the computer would cause a Computational error (C62 or C63) to appear on the screen and the program would immediately terminate.

The IF ... THEN statement is another way by which the programmer can instruct the program to process statements out of sequence. Here, Line 200 tests to determine whether the divisor, B, is greater than or less than zero. If the divisor is not zero, this statement is true, and the program skips to Line 220, where the program computes the quotient and is sent back to Line 110 to display it. If the divisor is zero, this statement is false, and the program will fall through to Line 210, the message will be displayed, and control is sent back to Line 20. Thus, the division computation is not performed.

Refer to Chapter 3 of *Programming in BASIC* and Chapter 11 of the Wang *BASIC-2 Language Reference Manual* for more information on the IF ... THEN statement.
Line 110:

110 PRINT A; A$; B; “EQUALS ”; C

In Line 110, as in Line 40, variable values and a literal are included in a PRINT statement. Here, there are three numeric variables (A, B, and C), an alphanumeric (A$), and a literal (“EQUALS ”).

Line 120:

120 INPUT “DO YOU WANT ANOTHER OPERATION”, B$

Line 120 requests a value for alphanumeric variable B$.

Lines 130-160:

130 IF STR(B$,1,1) = “Y” THEN 20
140 IF STR(B$,1,1) = “N” THEN 160
150 GOTO 120
160 END

Lines 130 and 140 introduce another function of which BASIC-2 is capable, that is, isolating a particular character from an alphanumeric string. In this case, the program examines the value of the first character in variable B$ for the character “Y” or the character “N”. By examining the first character of the string instead of every character, Lines 130 and 140 enable the user to continue the program by entering the abbreviated answer Y or N as well as the answer YES or NO to the question asked in Line 120.

In short, Line 130 means: if the first character from the first character of alphanumeric variable B$ is equal to Y, then go to Line 20. If the operator enters Y or YES (or, because of first character isolation, any word beginning with Y), the first character will be Y, and will send the program back to Line 20. A similar logic is exhibited in Line 140. In this case, if the first character of the response is N, the program is sent to statement 160, an END statement, causing the program to end.

However, if the first character of B$ is other than Y or N, the program will fall through to Line 150. There, the program will be sent back to Line 120. This procedure guarantees that the operator responds correctly, at least insofar as the first character of the response is either Y or N.

Refer to Chapter 5 of the Wang BASIC-2 Language Reference Manual for more information on the STR function.

Saving the Program on Diskette

To save this program on diskette, load a new diskette into the diskette slot of the diskette drive, format it, and establish a catalog as detailed in Chapter 3 of this manual. Enter the following command.

SAVE T/xxx, “ADDING”
The device address of the diskette where the program is to be saved is xxx. Then enter the command, LIST DCT. The following will appear on the screen.

\[
\begin{align*}
\text{INDEX SECTORS} & = 00030 \\
\text{END CAT. AREA} & = 03977 \\
\text{CURRENT END} & = 00029 \\
\text{NAME TYPE START END USED FREE} \\
\text{ADDING P 00029 00033 00005 00000}
\end{align*}
\]

Listing the Catalog Index ensures that the program you saved is in fact contained on the diskette.

Refer to the Wang BASIC-2 Disk Reference Manual for more information on saving programs on disk.

**Retrieving the Program from Diskette**

First, type in the following command.

\[\text{SELECT DISK xxx}\]

The device address of the disk containing the program to be retrieved is xxx. The system will select the system diskette drive. Then type the following command.

\[\text{LOAD RUN "ADDING"}\]

The adding machine program will first be loaded, and then run.

**Modifying the Program**

There are several ways in which the adding machine program can be improved. One of the program's major difficulties occurs when a user enters something other than +, -, X, or / in response to the request to enter the type of operation to be performed. If, for instance, someone entered 999 in response to \text{WHAT TYPE OF OPERATION (+,-,X,/) DO YOU WANT TO PERFORM?}, two things occur. Firstly, the last two nines are cut off, due to the DIM statement in Line 10. Secondly, when Line 40 is executed, 9 will actually appear in place of an operational sign on the CRT screen. The program will continue processing until it reaches Line 100. At that point, since the value of A$ is neither +, -, X, nor /, the program loops back to Line 20 to request the type of operation again.

The LINPUT statement is often used to avoid the first situation, the POS function can rectify the second.

First, replace Line 20 with the following.

\[\text{:20 LINPUT "WHAT TYPE OF OPERATION (+,-,X,/) DO YOU WANT TO PERFORM"-A$}\]
Then, insert Line 25.

:25 IF POS("+ -X/" = A$) = 0 THEN GOTO 20

Finally, delete Line 100 by typing the following.

:100

When this version of the program is run, the LINPUT statement in Line 20 causes an underscore to follow the prompt to enter the operational sign. The LINPUT statement also ensures that the operator only enter one character in response to this prompt.

The POS function causes the system to locate the position of the variable, A$, in the character string "+ -X/". If the operator enters + for the variable A$, POS("+ -X/" = A$) will equal 1, since + is in the first position of the character string in the POS function. Likewise, -, X, and / will equal 2, 3, and 4, respectively. A character other than one of these has no position in the character string and is equal to 0. If the operator enters such a character, the IF ... THEN statement in Line 25 will cause the program to go back immediately to Line 20 and request the operational sign to be entered again.

Resaving the Modified Program

To resave the modified program, the old program must first be scratched. This can be done by first pressing RESET. Then, enter the following command.

SCRATCH T/xxx, "ADDING"

T/xxx is the device address of the diskette containing the old program. Next, enter the following command.

SAVE T/D10, "ADDING"

T/xxx is the device address of the modified program. This command will copy the new version of the program called ADDING over the old version, saving it under the same name. Subsequently, when LOAD RUN DCT/xxx "ADDING" is executed, the new version of the adding program will be loaded.
CHAPTER 5
SYSTEM ERRORS AND ERROR-RECOVERY PROCEDURES

5.1 TYPES OF SYSTEM ERRORS

There are two different types of system errors which may occur on the 2200MVP: CPU hardware errors which indicate malfunctions in the CPU hardware (registers, user and control memory, etc.), and general system errors which indicate that an illegal operation has been attempted or a desired operation cannot be performed. Correspondingly, the 2200MVP CPU performs two different types of system error diagnostics: the CPU/hardware error diagnostics and the general system error diagnostics. The CPU/hardware errors are discussed in this chapter. If a CPU/hardware error occurs, the error display, which always appears on Terminal 1, should be written down. This information will enable the Wang service representative to quickly locate the malfunctioning components, if the error cannot be corrected by the general recovery procedures outlined in this chapter or if the error recurs intermittently. When the general procedures fail, try the specific procedures discussed in Appendix E. If the procedures in Appendix E fail or error conditions recur, call your Wang service representative.

The CPU hardware error diagnostics are designed to detect and report any malfunction which occurs in the CPU hardware (e.g., registers, and user and control memory). The CPU error-checking routines of the 2200MVP treat the entire CPU as a single unit since memory errors can affect all users of the system. The current configuration scheme does not affect the error-checking routines or error-recovery procedures. Whenever a location in memory is accessed, the system automatically performs a parity check to ensure that the accessed memory contents are valid and the accessed location is not faulty. Additionally, whenever RESET or CLEAR is executed, the entire memory is automatically verified, and the operator is alerted to any memory error condition. If a hardware error is discovered, all the terminals sound an audible tone and a system error message is displayed at Terminal 1. Although there are several courses of action, the hardware errors require that a corrective procedure be performed at Terminal 1.

General error messages, however, are designed to alert the user that an illegal operation has been attempted or a desired operation cannot be performed. Those general system errors which are not hardware related can be handled under program control in a user-application program. The general error routines are handled separately for each partition. The error message is displayed on the terminal which is currently attached to the partition in which the error occurred. If the error occurs while the partition is running a background job, the error-message display is suppressed until the terminal is released to the background partition. General error messages are signaled by an audible tone and a display on the CRT of the terminal attached to the partition in which they occur. Error messages consist of a two-digit number with a letter prefix accompanied by an arrow which points to the approximate location of the error in an Immediate mode or Program mode line. The types of general error diagnostics which are performed by the system and the techniques for recovering from such errors are described in detail in the BASIC-2 Language Reference Manual.
CPU Hardware Errors

Several possible system error messages can be reported when CPU/hardware errors occur during Master Initialization or once the operating system has assumed control of program execution. These hardware errors cannot be handled under program control. Since a hardware error represents a system hardware malfunction which may be transient, any information which the system furnishes or receives after the hardware error has occurred may be invalid. The procedures for recovery from these errors are detailed in the following section.

Master Initialization Error Recovery

The general procedure to recover from Master Initialization errors appears below. When these general procedures fail, call your Wang service representative.

1. When the system's power is turned on, the bootstrap fails to display the complete MOUNT SYSTEM PLATTER PRESS RESET message on the CRT. This condition usually indicates a CPU-related or I/O-related error. Turn the system’s power off and check the cabling and device addresses. Wait five seconds, then power the system up again. Do not turn the terminal off when performing this procedure.

2. Having responded to the KEY SF? message by pressing a Special Function key, the following conditions may exist.

   a. The hex-digit display of the Special Function key did not appear on the CRT, implying that the Special Function key was not pressed sufficiently or the wrong Special Function key was pressed. Press RESET and then press the desired Special Function key again.

   b. The KEY SF? message reappears upon the CRT. This error implies that the specified system file could not be located on the specified disk. Verify that the system platter is properly mounted at the specified address, and press the desired Special Function key again.

   c. The ***SYSTEM ERROR (DISK 00XX)*** PRESS RESET message appears. This error message implies that the wrong Special Function key was pressed or a disk hardware error occurred while the bootstrap was trying to load the disk file specified by the Special Function key. Make sure the platter is properly mounted, and press RESET and then the desired Special Function key. If the general procedure fails, refer to the table of disk errors in Appendix E for a specific recovery procedure.

General Hardware Error Recovery

A system error message is reported by an audible tone at each terminal and a display on the CRT of Terminal 1 whenever the operating system detects a memory error during its normal operation. A memory failure causes the following message to appear at Terminal 1.
*** SYSTEM ERROR (MMMM XXXX)***
PRESS RESET

AECM - Addressing Error Control Memory
AEDM - Addressing Error Data Memory
BECM - Bit Error Control Memory
BEDM - Bit Error Data Memory

where MMMM =  
PECM - Parity Error Control Memory
PEDM - Parity Error Data Memory
REDM - Read Error Data Memory
VECM - Verify Error Control Memory
VEDM - Verify Error Data Memory

and  XXXX = Location and Nature of Error

The general procedure used to recover from system errors in user and/or control memory is shown below. When the general procedure outlined here fails, refer to the table of system and disk errors in Appendix E for more detailed recovery procedures. If the detailed recovery procedures fail or a system error condition recurs, call your Wang service representative.

Press RESET in response to the PRESS RESET message on Line 1 of the CRT, and then choose one of the following three procedures in response to the SF Key message on the CRT.

1. Press SF'16-'19 to load the diagnostic menu from which you may choose the applicable diagnostic (refer to Section 5.2). Although this procedure is recommended, execute Procedure Number 3 if the current contents of user memory cannot be reproduced (i.e., must be salvaged). If no errors are discovered during the execution of the hardware diagnostics, the error condition can be presumed transient. Proceed with Procedure Number 2. Note that with Procedure Number 2, the contents of user memory are erased.

2. First, power down, then power up, then press SF'00-'03 to load BASIC-2 from Disk D11 (310), D10 (B10), D21 (320), or D20 (B20), respectively, in order to start over again. This is the recommended procedure when the system validity has been compromised by an unknown system error, but the condition at fault is suspected to be temporary and does not require execution of a diagnostic routine. For example, the CPU was jarred or a cable was stepped on or shaken loose. This option should be exercised when there is no need to save the current contents of user memory. The 2200MVP must now be reconfigured with the @GENPART utility to resume multi-user operation.

3. Press SF'15 to resume normal operation, using the operating system and application program currently loaded. This option should be exercised when the user-memory contents cannot be duplicated and must therefore be salvaged. The system will be returned (if possible) to Console Input mode and the READY BASIC-2 message will be displayed. Since user memory was not erased, the user can now determine the point of program execution, when the system error was encountered in the current application program, by printing out the key variables. However, since a reset has been performed on one of the partitions, program execution may not be able to be continued from that point, but must be restarted with a Run command. This procedure is undertaken at the user's risk, however, since the hardware error may recur and the operating system may not function properly.
5.2 USING THE HARDWARE DIAGNOSTICS

As with Master Initialization, the hardware diagnostics can only be executed at Terminal 1. The hardware diagnostics are a set of programs which exhaustively test the CPU hardware components and attempt to identify any malfunctions. The diagnostics can be run only after Master Initialization or a system error has occurred. The diagnostics run continuously until RESET is pressed or an error is detected. When an error is detected, diagnostic processing stops, or an error message is displayed. For a discussion of possible error causes, refer to Appendix E. If a hardware error recurs, call your Wang service representative.

A hard copy listing of the diagnostic messages can be obtained by turning on the printer attached to the CPU during diagnostic execution. The printer attached to the CPU must be assigned Address 215 or 204 and SELECTed (press SELECT on the printer). A hard copy trace of the diagnostic run should be obtained because it will help your Wang service representative locate and correct any problems. If no errors occur, the output will be comprised of only the name of the current test. When errors occur, they will be printed under the appropriate diagnostic test title.

Since the diagnostic programs destroy the contents of user memory, the user should save all valuable programs and data on disk prior to running the diagnostics.

The diagnostic programs of this system should be executed:

- At least once every 60 to 100 hours of light-to-normal operation.
- Whenever errors cause a hardware malfunction to be suspected.
- Whenever a Wang service representative requests their execution.

It is best to execute the diagnostic routines as quickly as possible, after observation of a suspected problem, to ensure that the environmental conditions of the test most closely resemble those under which the problem occurred.

Random intermittent problems and permanent component failure are often due to static electricity, EMI, temperature and humidity extremes, and excessive airborne dust and dirt. Prolonged operation in a poor environment produces permanent failure. Every effort should be made to secure an environment which, if not optimal, at least provides the operating conditions required for satisfactory system performance.

Table 5-1 provides a functional description of each diagnostic. Press RESET and then press the appropriate Special Function key (SF‘16 - ‘19), after each diagnostic, in order to select another diagnostic. To reselect BASIC-2, press SF‘00 - ‘05.

Loading the Diagnostics Menu

If the system is on, turn it off. Then, turn the system on, press RESET, and then press one of the following Special Function keys.

SF Key '16 - Load diagnostics from Disk D11 (or 310)
SF Key '17 - Load diagnostics from Disk D10 (or B10)
SF Key '18 - Load diagnostics from Disk D21 (or 320)
SF Key '19 - Load diagnostics from Disk D20 (or B20)

The following display appears upon selection of the Diagnostic menu (SF Key '16, '17, '18, or '19).

KEY SF
USER DIAGNOSTIC MENU
'00 CPU DIAGNOSTIC
'01 CONTROL MEMORY DIAGNOSTIC
'02 DATA MEMORY DIAGNOSTIC

Press the appropriate Special Function key to load the desired diagnostic.

The CPU Diagnostic

This diagnostic tests the 2200MVP processor. This test runs continuously until either an error occurs (the pass number stops incrementing) or RESET is pressed. If an error occurs, call your Wang service representative. When a sufficient number of successful test passes have occurred (at least five to ten), press RESET. The Diagnostics menu can be restored to the screen, or BASIC-2 can be reloaded by pressing the appropriate Special Function key.

The Control Memory Diagnostic

This diagnostic is designed to test the control memory. These control memory diagnostic tests are repeated until RESET is pressed. Error messages will be displayed or printed whenever memory failures are discovered. When a sufficient number of successful test passes have occurred (at least five to ten passes), press RESET. The Diagnostics menu can then be restored to the screen, or BASIC-2 can be loaded by pressing the appropriate SF key.

The Data (User) Memory Diagnostic

This diagnostic is designed to test data (user) memory. The user memory diagnostic tests are also repeated until RESET is pressed. Error messages will be displayed or printed whenever memory failures are discovered. When a sufficient number of successful test passes have occurred (at least five to ten passes), press RESET. At the completion of the diagnostic tests, the operator can pass control to the BASIC-2 operating system by pressing RESET, then pressing the appropriate Special Function key to load the operating system.
APPENDIX A
SYSTEM SPECIFICATIONS

A.1 2200MVP CPU SPECIFICATIONS

CPU Size
Height ................................................................. 16.0 in. (40.6 cm)
Width ................................................................. 24.8 in. (63.0 cm)
Depth ................................................................. 10.5 in. (26.7 cm)
9 I/O Ports

Weight
47 lb (21 kg)

Memory Size
32K bytes (standard)
Expandable to 64K, 128K, 192K, or 256K bytes

Power Requirements
115 VAC ± 10%, 50 or 60 Hz ± 1 Hz
230 VAC ± 10%, 50 or 60 Hz ± 1 Hz
230 watts

Fuses
3.0 amps at 115 V
1.5 amps at 230 V

Operating Environment
60° F to 80° F (15° C to 27° C)
40% to 60% relative humidity (recommended)

Dynamic Range
\(-10^{100} < n < = -(10^{-99}), 0, (10^{-99}) < = n < (10^{+100})\)

Precision
13 digits (standard)

A.2 MODEL 2236DE INTERACTIVE TERMINAL SPECIFICATIONS

Size
Height ..................................................................... 13.5 in. (34.3 cm)
Depth ..................................................................... 20.5 in. (52.1 cm)
Width ..................................................................... 19.8 in. (50.3 cm)

Weight
51 lb (23.1 kg)
CRT
Display Size .................................................. 12 in. diagonal (30.5 cm)
Capacity ...................................................... 24 lines, 80 characters/line
Character Height ........................................... 0.16 in. (0.41 cm)
Character Width ............................................ 0.09 in. (0.23 cm)

Character Set
128 characters, including uppercase and lowercase letters

One or more attributes per character for high- or low-intensity display, blinking, reverse video, or underlining

Additional alternate character set consisting of 64 graphic characters and other special symbols

Line-segment (box) graphics, separate from either character set

Keyboard
Typewriter keyboard generating 88 different ASCII characters, including uppercase and lowercase letters, numbers, and symbols

Numeric keypad

Several Program Control keys

17 user-definable Special Function keys (16 numbered keys along the top of the keyboard and 1 key labeled FN located in the upper-left corner of the alphanumeric keyboard zone), which when used with the SHIFT key, total 34 Special Function keys

Operating Environment
50° F to 90° F (10° C to 32° C)
35% to 65% relative humidity, noncondensing (recommended)
20% to 80% relative humidity, noncondensing (allowable)

Power Requirements
115 or 230 VAC ± 10%
50 or 60 Hz ± 1.0 Hz
50 watts

Fuses
2 amps (SB) at 115 V/60 Hz
1 amp (SB) at 230 V/50 Hz

Communication Mode
Asynchronous, full-duplex

Transmission Rates
Manually selectable for each terminal at 300, 600, 1200, 2400, 4800, 9600, or 19.2K baud
Character Format
When communicating with a 2200LVP, 2200MVP, 2200SVP, or 2200VP system:
  1 start bit, 1 stop bit, 8 data bits, plus odd parity (11 bits/character)

Other selectable character formats:
  8 data bits, no parity
  7 data bits, odd parity
  7 data bits, even parity (10 bits/character)

Terminal/CPU Cable
One 8-ft (2.4-m) cable to power source

One 25-ft (7.6-m) direct connection cable provided with each 2236D-type terminal, unless an optional direct connection cable is ordered

Nonextendable cables (refer to Table A-1) available (optionally) for direct connection up to 2,000 ft (606.1 m)

A.3 MODEL 2236MXD TERMINAL PROCESSOR SPECIFICATIONS

Operating Environment
Same as for 2200MVP CPU

Power Requirements
Supplied by CPU

Communication Modes
Full-duplex, asynchronous for Model 2236DE Interactive Terminals

Transmission Rates
300, 600, 1200, 2400, 4800, 9600, or 19.2K baud

Asynchronous Communication Character Format
Odd parity bit, 8 data bits, 1 stop bit, and 1 start bit

Number of CPU I/O Slots
One I/O slot required
Up to four terminals supported
APPENDIX B
AVAILABLE PERIPHERALS

The 2200MVP will support most peripheral devices currently listed on the standard products price list, except unbuffered and time-dependent devices. For example, some exclusions include certain instrument interfaces, the Model 2209 9-Track Tape Drive, the Model 2210 and 2226 Consoles, the Model 2202 Printer, and the Disk Controller 22C31 (Triple Controller). A list of supported devices (as of the publication date of this manual) follows.

<table>

APPENDIX C
PREVENTIVE MAINTENANCE AND ENVIRONMENTAL CONSIDERATIONS

C.1 PREVENTIVE MAINTENANCE

It is recommended that the equipment be serviced semi-annually; a Maintenance Agreement is available to assure this servicing automatically. If no Maintenance Agreement is acquired, any servicing must be arranged for by the customer. A Maintenance Agreement protects the customer’s investment and offers the following benefits.

- Preventive Maintenance — The equipment is inspected semi-annually for worn parts, adjusted, lubricated, cleaned, and updated with any engineering changes. Preventive maintenance minimizes downtime by anticipating repairs before they are necessary.

- Fixed Annual Cost — When a Maintenance Agreement is bought, only one purchase order for service is issued for an entire year and one annual billing is received. More frequent billing can be arranged, if desired.

Further information regarding Maintenance Agreements can be acquired from your local Wang Sales/Service Office.

NOTE

Wang Laboratories, Inc., neither honors maintenance agreements for, nor guarantees, any equipment modified by the user. Damage to equipment incurred as a result of such modification is the financial responsibility of the user.

C.2 ENVIRONMENTAL CONSIDERATIONS

When the recommended temperature range is exceeded, both component failure rates and the loss of data through distortion of data storage materials are likely to increase.

Airborne contaminants can accumulate rapidly on the circuit boards and their components, forming a film which not only prevents adequate heat dissipation from the electronic elements, but also creates leakage paths, causing errors in the system signals. Additionally, dust will cause excessive wear in the disk read/write heads and the oxide coatings of storage media. The filters of all HVAC (heating, ventilating, air conditioning) equipment should be cleaned or replaced regularly. In areas where these filters do not sufficiently remove airborne contaminants, an electrostatic air filter should be installed.
Low humidity increases the probability of static buildup, causes oxide shed in data storage materials, and increases the static charge imparted to carpets and clothing. When the operator comes in contact with the system, the resultant static discharge, which could be several thousand volts, will also cause system errors or destruction of data. High humidity rapidly deteriorates paper stock and magnetic disks and tape. Humidifiers or dehumidifiers should be installed in the environment’s heating, ventilating, and air conditioning systems as required.

Carpeting to be installed should be a nonstatic variety. Static carpeting that is already installed must be treated with nonstatic spray, or an electrically conductive mat should be installed under the system operating area and be properly connected to an earth ground to prevent static buildup.

Computers and peripherals are susceptible to malfunction due to electromagnetic interference (EMI) from devices such as radio transmitters and industrial motors. EMI can enter the system by conduction through wiring and cabling or by direct radiation. An illustration of EMI is a television which becomes full of “snow” when a car with a poorly tuned engine idles outside (radiated EMI) or someone turns on a hair dryer or vacuum cleaner in the next room (conducted EMI). To minimize such interference, the three-prong AC power line should be dedicated to the system, grounded, properly installed in a steel conduit, and isolated from interference-generating devices like office machines, fluorescent lighting, motors, and HVAC units. If these devices are located near the system area, they must be relocated, repaired, or filtered to ensure that they do not disturb the system. (EMI filters, isolation transformers, and line conditioners should be installed on the system’s AC power line.) In cases of high residual EMI, it may also be necessary to shield all peripheral cables.

The recommended operating environment is defined by the following parameters.

Temperature:  50° F to 90° F (10° C to 32° C).
Relative Humidity:  35% to 65%, noncondensing.
Dust:  No obvious accumulation in a 24-hour period.
Power:  Grounded, noise-free, dedicated 115 or 230 VAC ± 10%, 50 or 60 Hz ± 1.0 Hz.
Interference:  All sources of static electricity, extreme magnetism, and EMI shall be controlled.

A list of additional considerations which should be heeded follows.

• Keep an accurate service history on all equipment.

• Avoid consuming food and beverages, smoking, and performing any other activity not related to operation of the system while near the equipment.

• Avoid touching magnetic disks and tape or exposing them to direct sunlight, strong magnetic fields, or freezing temperatures. If subjected to extremes, allow the media to return to normal operating conditions before use (24 hours is recommended), and test the media thoroughly.

• Return the diskette to its storage envelope whenever it is removed from the drive. Replace the storage envelopes when they become worn, cracked, or distorted. The envelopes are designed to protect the diskette.
• Date the media when first used, since media over two years old should be replaced. Use felt-tip pens to write on the media label. Never use an eraser to alter a label; instead, use a new label.

• Always make a duplicate copy (backup) of tapes and diskettes, and then store the backup safely in a different area.

**NOTE**

Most Wang electrical devices are equipped with an exhaust fan and entry vents. These vents and fan should not be obstructed. Therefore, never place system equipment immediately adjacent to file cabinets or other surfaces which might impede proper air flow.
APPENDIX D
CONTROL CODES AND CHARACTER SETS

The following charts show the control codes (Table D-1), the character set (Figure D-1), and the alternate character set (Figure D-2) for the 24-line by 80-character-per-line CRT of the Model 2236DE Console. In the normal character set, the codes HEX(90) to HEX(FF) are underlined versions of characters from HEX(10) to HEX(7F). Thus, adding HEX 80 to a non-underlined character’s HEX value, yields the HEX code of its underlined counterpart.

**Figure D-2. The Alternate Character Set**
APPENDIX E
SYSTEM HARDWARE ERROR MESSAGES AND RECOVERY PROCEDURES

E.1 DISK ERROR MESSAGES AND RECOVERY

The following discussion explains the significance of each system error and suggests possible recovery procedures. If these procedures fail, call your Wang service representative. A system error is usually serious enough to warrant executing a control memory diagnostic. However, it may be possible to resume execution of the currently loaded application program by pressing RESET and then SF '15. If the error is reported again, a memory diagnostic should be run to locate the defective memory location.

Several possible disk errors may occur while trying to load disk information. The recommended recovery procedure involves consulting the following description of each possible disk error to determine if the problem can be corrected and then attempting to reload. Should successive failures occur, call your Wang service representative. All disk errors are more fully documented in the Wang BASIC-2 Disk Reference Manual and the Wang BASIC-2 Language Reference Manual.

ERR D82

Error: FILE NOT IN CATALOG
Cause: A nonexistent file name was specified, or an attempt was made to load a data file as a program file or a program file as a data file.
Recovery: Make sure the correct file name is being used, the proper disk platter is mounted, and the proper drive is being accessed.

ERR I90

Error: DISK HARDWARE ERROR
Cause: The disk did not respond properly to the system at the beginning of a read or write operation; the read or write has not been performed.
Recovery: Press RESET and run the program again. If the error persists, ensure that the disk unit is powered on and that all cables are properly connected. If the error still occurs, contact your Wang service representative.
ERR I91

Error: DISK HARDWARE ERROR

Cause: A disk hardware error occurred because the disk is not in file-ready position. If the disk is in Load mode or if the power is not turned on, for example, the disk is not in file-ready position and a disk hardware error is generated.

Recovery: Press RESET and run the program again. If the error recurs, check to ensure that the program is addressing the correct disk platter. Be sure the disk is turned on, properly set up for operation, and that all cables are properly connected. Set the disk into Load mode and then back into the Run mode by using the procedure specified for the disk drive. If the error persists, call your Wang service representative.

NOTE
The disk must never be left in Load mode for an extended period of time when the power is on.

ERR I92

Error: TIMEOUT ERROR

Cause: The device did not respond to the system in the proper amount of time (time-out). In the case of the disk, the read or write operation has not been performed.

Recovery: Press RESET and run the program again. If the error persists, be sure that the disk platter has been formatted. If the error still occurs, contact your Wang service representative.

ERR I93

Error: FORMAT ERROR

Cause: A format error was detected during a disk operation. This error indicates that certain sector-control information is invalid. If this error occurs during a read or write operation, the platter may need to be reformatted. If this error occurs during formatting, there may be a flaw on the disk’s surface.

Recovery: Format the disk platter again. If the error persists, replace the media. If the error continues, call your Wang service representative.
ERR 194
Error: FORMAT KEY ENGAGED
Cause: The disk format key is engaged. The key should be engaged only when formatting a disk.
Recovery: Turn off the format key.

ERR 195
Error: DEVICE ERROR
Cause: A device fault occurred, indicating that the disk could not perform the requested operation. This error may result from an attempt to write to a write-protected platter.
Recovery: If writing, make sure the platter is not write-protected. Repeat the operation. If the error persists, power the disk off and then on, and then repeat the operation. If the error still occurs, call your Wang service representative.

ERR 196
Error: DATA ERROR
Cause: For read operations, the checksum calculations (CRC or ECC) indicate that the data read is incorrect. The sector read may have been written incorrectly. For disk drives that perform error correction (ECC), the error correction attempt was unsuccessful. For write operations, the Longitudinal Redundancy Check (LRC) calculation indicates that the data sent to the disk was incorrect. The data has not been written.
Recovery: For read errors, rewrite the data. If read errors persist, the disk platter should be reformatted. For write errors, the write operation should be repeated. If write errors persist, ensure that all cable connections are properly made and are tight. If either error persists, contact your Wang service representative.

ERR 197
Error: LONGITUDINAL REDUNDANCY CHECK ERROR
Cause: A longitudinal redundancy check error occurred when reading or writing a sector. Usually, this error indicates a transmission error between the disk and the CPU. However, the sector being accessed may have been previously written incorrectly.
Recovery: Run the program again. If the error persists, rewrite the flawed sector. If the error still persists, call your Wang service representative.
ERR I98

Error: ILLEGAL SECTOR ADDRESS OR PLATTER NOT MOUNTED

Cause: The disk sector being addressed is not on the disk, or the disk platter is not mounted. (The maximum legal sector address depends upon the disk model used.)

Recovery: Correct the program statement in error, or mount a platter in the specified drive.

ERR I99

Error: READ-AFTER-WRITE ERROR

Cause: The comparison of read-after-write to a disk sector failed, indicating that the information was not written properly. This error usually indicates that the disk platter is defective.

Recovery: Write the information again. If the error persists, try a new platter; if the error still persists, call your Wang service representative.

E.2 SYSTEM (EXECUTION) ERROR MESSAGES

The system initially checks each text line for various types of errors as the line is entered by the programmer during program resolution and execution. The system responds to an error condition by producing an audible tone, terminating the current operation immediately, displaying the erroneous line, and presenting beneath it the message ERR followed by an error code, with an arrow pointing to the approximate position of the error. Note that the system stops error scanning when the first error is detected. Thus, if a line contains more than one error, only the first is detected and reported by the system. Some errors can be recovered under program control.

The error codes with a two-digit number preceded by a letter prefix (e.g., A04) are the type that occur once the system program has been given control. The letter identifies the particular class of errors to which the error belongs, while the two-digit number identifies the specific error condition. (For example, an error commonly encountered during text entry is S13, Missing Comma. The S indicates a syntax error, and the 13 identifies the error uniquely as Missing Comma.) There are seven classes of error conditions, each identified by a unique letter prefix in the error code. These error classes and the letter prefixes which identify them follow.

<table>
<thead>
<tr>
<th>Class of Errors</th>
<th>Letter Prefix</th>
</tr>
</thead>
<tbody>
<tr>
<td>Miscellaneous errors</td>
<td>A</td>
</tr>
<tr>
<td>Syntax errors</td>
<td>S</td>
</tr>
<tr>
<td>Program errors</td>
<td>P</td>
</tr>
<tr>
<td>Computation errors</td>
<td>C</td>
</tr>
<tr>
<td>Execution errors</td>
<td>X</td>
</tr>
<tr>
<td>Disk errors</td>
<td>D</td>
</tr>
<tr>
<td>I/O errors</td>
<td>I</td>
</tr>
</tbody>
</table>
See the complete list of the errors included in each class and their specific recovery procedures in the BASIC-2 Language Reference Manual.

Errors in the first three classes listed (Miscellaneous errors, Syntax errors, and Program errors) are detected during text entry or program resolution and cause the system to terminate the current operation and display an error message. The operator then must correct the error before proceeding with further operations. Errors of this kind are called nonrecoverable, because they cannot be recovered under program control.

Errors in the four remaining classes (Computation errors, Execution errors, Disk errors, and I/O errors) typically occur during program execution and can be recovered under program control without aborting the program or disrupting the display with an error message. Errors which can be intercepted by the program before the operating system intervenes are called recoverable errors. Three BASIC-2 instructions are provided for intercepting and responding to recoverable errors: the SELECT ERROR statement, the ERR function, and the ERROR statement.

APPENDIX F
CHANGING THE TRANSMISSION RATE OF THE
MODEL 2236DE INTERACTIVE TERMINAL
AND THE 2236MXD TERMINAL PROCESSOR

F.1  INTRODUCTION

NOTE

Wang Laboratories, Inc., does not guarantee any equipment modified by the user. Damage to equipment incurred as a result of such modification is the financial responsibility of the user. We recommend that only Wang customer engineers modify Wang equipment.

With all switch types, one end of the switch will be marked ON (-). The push-in type of switch has two white squares, one above and one below each switch's number. When a square at the ON end is pressed in, the switch is on and the opposite square projects out. The slide type of switch requires a sliding motion toward either the ON or OFF position. The rocker type switch operates similarly to the push-in type. When one end of the rocker switch is pushed in, the opposite end projects out. (Refer to Figure F-1 for an illustration of the three types of switches.)

Figure F-1. The Three Types of Switches
F.2 CHANGING THE TRANSMISSION RATE OF THE MODEL 2236DE TERMINAL

To change the data transmission rate of the 2236DE Interactive Terminal, observe the following procedure.

1. Switch the terminal’s power off.
2. Locate the cap in the rear of the terminal. If necessary, the terminal may be moved slightly to provide better access to the cap.
3. Using a screwdriver (as shown in Figure F-2), gently remove the cap by placing the tip of the screwdriver underneath it.
4. The transmission rate switch is now exposed. Note that any of the three switch types may be located on the terminal. When setting the switches, follow the instructions for whatever type of switch is installed in the terminal.

Figure F-2. Removing the Cap

5. The switch settings that correspond to each possible data transmission rate appear in Figure F-3. Set the three uppermost switches to the appropriate positions for the transmission rate desired.
Figure F-3. The Data Transmission Rate Switch Settings on the 2236DE Interactive Terminal

6. Set the number of data bits to eight and parity to ODD. All settings in Figure F-3 appear with eight data bits and odd parity. When using a 2200 system configuration, the number of data bits must be eight and the parity must be odd.

7. After setting the switches, place the cap back into position on the back of the terminal.

8. The terminal's power may now be switched on.

9. The terminal will display its power on message [2236DE R01 19200BPS 8 + 0 (USA)] so that the switch settings can be verified. (Refer to Section 3.7 for a discussion of this message.)

Users are reminded that whenever using a 2200 system, the number of data bits must be eight and the parity must be odd. However, a user may wish to change the number of data bits or the parity in order to be compatible with other systems. To change either the number of data bits or the parity, perform the following procedure.
To set the number of data bits, move the data bit switch:

- Left for seven data bits.
- Right for eight data bits.

To set the parity, move the parity switch:

- Left for odd parity with eight data bits.
- Left for odd parity with seven data bits.
- Right for no parity with eight data bits.
- Right for even parity with seven data bits.

F.3 CHANGING THE TRANSMISSION RATE OF THE 2236MXD TERMINAL PROCESSOR

To change the transmission speed of the Model 2236MXD, perform the following procedure.

1. Power the system down by turning off all terminals and printers, followed by all disk drives, the Disk Processing Unit (DPU), and finally the Central Processing Unit (CPU).

2. Loosen the retaining screws which attach the terminal processor to the CPU. Using the two handles on top of the processor, pull the processor board straight up and out of the CPU I/O port.

3. Locate the three, eight-bank switches on the processor board used to set the transmission rate (refer to Figure F-4). Note that any of the three switch types may be located on the processor. Follow the instructions for setting whatever type of switch is installed on the processor.

4. The switch position labeled 4800 baud actually specifies 19.2K bits per second (bps) in normal operation. If 4800 bps operation is required, then the board must be physically modified because the 19.2K-bps and 4800-bps rates are mutually exclusive. Contact Wang Customer Service for further details.

5. For each terminal, set the corresponding processor switch to the same data transmission rate set on the terminal. The 24 switches are divided into four sets (one set for each possible terminal). Each set is divided into six switches (one switch for each possible data rate of each terminal). (Refer to Figure F-4.)

6. After setting the switches, replace the terminal processor in the CPU I/O port and tighten the retaining screws.

7. The system may now be powered on. Begin by turning on the CPU, followed by the DPU, all disk drives, and lastly, all printers and terminals.
Figure F-4. The Transmission Rate Switch Settings on the 2236MXD Terminal Processor
APPENDIX G
SETTING THE DEVICE ADDRESS OF THE
2236MXD TERMINAL PROCESSOR

G.1 INTRODUCTION

NOTE

Wang Laboratories, Inc., does not guarantee any equipment modified by the user. Damage to equipment incurred as a result of such modification is the financial responsibility of the user. We recommend that only Wang customer engineers modify Wang equipment.

When one to four terminals are configured, one 2236MXD Terminal Processor is used. The address of the primary processor is always set at Address /00 (the processor also reserves Addresses 01 – 07). When five to eight terminals are configured, two 2236MXD Terminal Processors are required. The address of the second processor is always set at Address /40 (the processor also reserves Addresses 41 – 47). When nine to twelve terminals are configured, three 2236MXD Terminal Processors are required. The address of the third processor is always set at Address /80 (the processor also reserves Addresses 81 – 87).

Note that unlike other peripheral processors, the physical device address set on the 2236MXD Terminal Processor is not the address specified in a program for access to the terminal CRT, keyboard, and local printers. The programmable device addresses for all terminals are: CRT /005, keyboard /001, and local printers /004. The operating system translates these programmable addresses into the appropriate physical processor address.

With all switch types, one end of the switch will be marked ON(-). The push-in type of switch has two white squares, one above and one below each switch’s number. When a square at the ON end is pressed in, the switch is on and the opposite square projects out. The slide type of switch requires a sliding motion toward either the ON or OFF position. The rocker type of switch operates similarly to the push-in type. When one end of the switch is pushed in, the opposite end projects out. (Refer to Figure F-1 for an illustration of the three types of switches.)

G.2 SETTING THE DEVICE ADDRESS

To set the terminal processor’s physical device address, perform the following procedure.

1. Power the system down by turning off all terminals and printers, followed by all disk drives, the Disk Processing Unit (DPU), and finally the Central Processing Unit (CPU).
2. Loosen the retaining screws which attach the processor to the CPU. Using the two handles on top of the processor, pull the processor board straight up and out of the CPU I/O port.

3. Locate the five-bank switch on the processor board used to set the device address (refer to Figure F-4). Note that any of the three switch types may be located on the processor. Follow the instructions for setting whatever type of switch is installed on the processor.

4. For each processor, set the device address as required.
   a. To set the address at /00—place all switches in the OFF position. Refer to Figure G-2. (An address of /00 indicates the primary 2236MXD Terminal Processor which controls Terminals 1-4.)
   b. To set the address at /40—place the 40 switch in the ON position; place all other switches in the OFF position. Refer to Figure G-3. (An address of /40 indicates that there are two 2236MXD Terminal Processors. The second processor, which must be set at /40, controls Terminals 5-8.)
   c. To set the address at /80—place the 80 switch in the ON position; place all other switches in the OFF position. Refer to Figure G-4. (An address of /80 indicates that there are three 2236MXD Terminal Processors. The third processor, which must be set at /80, controls Terminals 9-12.)

5. After setting the address, reinsert the processor in the CPU I/O port and tighten the retaining screws.

![The Device Address Switch on the 2236MXD Terminal Processor](image)

Figure G-1. The Device Address Switch on the 2236MXD Terminal Processor
6. The system may now be powered on. Begin by turning on the CPU, followed by the DPU, all disk drives, and finally, all printers and terminals.

![Figure G-2. Device Address /00](image)

![Figure G-3. Device Address /40](image)

![Figure G-4. Device Address /80](image)

**NOTE**

Addresses 01 – 07, 41 – 47, 81 – 87, and C1 – C7 are reserved for the 2236MXD Terminal Processor and cannot be used for any other devices.
If the processor connectors are not numbered, they can be easily distinguished and identified. The two connectors nearest the handles on top of the processor are always offset such that the plug on one end will be closer to the handle than the plug on the other end of the processor. The jack which is closest to the handle has the highest number. The jack numbers descend sequentially from the end with the jack closest to the handle toward the opposite end of the processor board. (Refer to Figure G-5.)

Figure G-5. Determining the Number Assigned to the Jacks on the 2236MXD Terminal Processor
APPENDIX H
SETTING THE DEVICE ADDRESS
ON THE 22C32 TRIPLE CONTROLLER

H.1 INTRODUCTION

NOTE

Wang Laboratories, Inc., does not guarantee any equipment modified by the user. Damage to equipment incurred as a result of such modification is the financial responsibility of the user. We recommend that only Wang customer engineers modify Wang equipment.

The 22C32 Triple Controller has three switch banks for setting the device addresses of the printer, disks, and terminal. The disk switch bank is closest to the cable connectors, the printer is next, and the terminal switch bank is the lowest, with only five switches in the bank. (Refer to Figure H-1.)

With all switch types, one end of the switch will be marked ON(-). The push-in type of switch has two white squares, one above and one below each switch's number. When a square at the ON end is pressed in, the switch is on and the opposite square projects out. The slide type of switch requires a sliding motion toward either the ON or OFF position. The rocker type of switch operates similarly to the push-in type. When one end of the switch is pushed in, the opposite end projects out. (Refer to Figure F-1 for an illustration of the three types of switches.)

Figure H-1. The Device Address Switches on the 22C32 Triple Controller
H.2 SETTING THE DEVICE ADDRESS

The standard disk address is 10. However, the address can be set to 20 or 30 if more than one disk is attached to the system. Refer to Figure H-2.

![Figure H-2. Disk Address 10](image)

The standard printer address is 15. However, if more than one printer is attached to the CPU, Addresses 16 or 17 can be used. Refer to Figure H-3.

![Figure H-3. Printer Address 15](image)

Whenever setting the address of the terminal, Switch 1 must always be placed in the ON position. If Switch 1 is in the OFF position, the terminal controller is disabled and only the printer and disk can be used.

On single-terminal systems, the 40 and 80 bits of the switch are always placed in the OFF position (the controller then responds to Addresses 01 – 07). Refer to Figure H-4.

![Figure H-4. Switches Set for Terminal 1](image)
On five-terminal 2200MVP systems, the 22C32 Triple Controller should be used for the fifth terminal. The switches should be set such that the 40 bit is ON and the 80 bit is OFF (the controller then responds to Addresses 41 – 47). Refer to Figure H-5.

![Figure H-5. Switches Set for Terminal 5](image)

On nine-terminal 2200MVP systems, the 22C32 Triple Controller should be used for the ninth terminal. The switches should be set such that the 80 bit is ON and the 40 bit is OFF (the controller then responds to Addresses 81 – 87). Refer to Figure H-6.

![Figure H-6. Switches Set for Terminal 9](image)

On 13-terminal 2200MVP systems, the 22C32 Triple Controller should be used for the thirteenth terminal. The switches should be set such that both the 40 and 80 bits are ON (the controller then responds to Addresses C1 – C7). Refer to Figure H-7.

![Figure H-7. Switches Set for Terminal 13](image)
Note that unlike other peripheral controllers, the physical device address set on the terminal controller is not the address specified in a program for access to the terminal CRT, keyboard, and local printers. The programmable device addresses for all terminals are: CRT, /005; keyboard, /001; and local printers, /004. The operating system translates these programmable addresses into the appropriate physical controller addresses.

To set the physical device address of the 22C32 Triple Controller, perform the following procedure.

1. Power the system down by turning off all terminals and printers, followed by all disk drives, the Disk Processing Unit (DPU), and finally the Central Processing Unit (CPU).

2. Loosen the retaining screws which attach the controller to the CPU. Using the two handles on top of the controller, pull the controller board straight up and out of the CPU I/O port.

3. Locate the appropriate switch on the controller board used to set each device address. Note that any of the three switch types may be located on the controller. Follow the instructions for setting whatever type of switch is installed on the controller.

4. Set the device addresses as desired. (Refer to Figures H-1 to H-7).

5. After setting the addresses, reinsert the controller in the CPU I/O port and tighten the retaining screws.

6. The system may now be powered on. Begin by turning on the CPU, followed by the DPU, all disk drives, and finally, all printers and terminals.

---

**NOTES**

Addresses 01 – 07, 41 – 47, 81 – 87, and C1 – C7 are reserved for the 2236MXD Terminal Processor and 22C32 Triple Controller and **cannot** be used for any other devices.

The transmission rate of the 22C32 Triple Controller is preset at 19.2K bps and cannot be modified.
APPENDIX I
WANG IBM COMPATIBILITY SOFTWARE FEATURES (OPTIONAL)

Because of the 2270A Diskette Drive hardware, IBM 3740 Diskette compatibility is possible. However, because of the different file formats used by Wang and IBM, either Wang or user-written software must be run to utilize this compatibility feature. Wang optionally supports disk utility programs and subroutines to maintain files in IBM 3740 format. The subroutines, when appended to a user-written program, require about 4.5K bytes. Use of the entire Wang software system requires about 12K bytes. If the IBM compatibility feature is to be used, at least two diskette drives are recommended. One is needed for mounting the 3740 Diskette, which will be used for data storage and retrieval, and another is needed for mounting the compatibility software. In addition to the extensive set of disk I/O instructions and the automatic file management system, Wang offers several optional utility software packages for the creation, sorting, and merging of disk data files.

Wang’s 3740 Diskette Compatibility Software, designed for use with the IBM 3740 Compatible Diskette Drive, provides a set of utility programs which implement operations such as:

- Displaying a 3740 Diskette catalog, thereby providing the names of stored files and the addresses of each file’s reserved and used sectors.
- Displaying 3740 sector dumps for the sectors in a specified address range.
- Performing media conversion of Wang disk/diskette files* to 3740 Diskette files or vice versa.
- Producing a hard copy of a specified 3740 Diskette file or a Wang diskette file previously converted from a 3740 Diskette.

The software also provides utility subroutines which can be integrated with the user-written BASIC-2 language application programs where 3740 Diskettes are to be accessed directly for file creation or maintenance. The subroutines handle the following types of operations.

- Opening a new or existing file
- Reading, rereading, or writing a sector
- Skipping or backspacing a specified number of sectors
- Writing or updating an end-of-data pointer position
- Closing a file

* The 3740 Diskette Compatibility Software processes telecommunications-formatted Wang files (maximum record length 128 bytes).
For detailed information concerning disk operations and BASIC-2 disk language features for all Wang disk models, see the Wang BASIC-2 Disk Reference Manual. For more information concerning the IBM compatibility features, obtain the IBM 3740 Compatibility Software Package (literature control number 195-1030-3), which contains a software diskette (literature control number 701-2212) and the 3740 Diskette Compatibility Software User Manual (literature control number 700-4369).
APPENDIX J
LOCAL AND REMOTE TERMINAL/CPU INTERFACE

J.1 LOCAL CONNECTION

Each 2236D-type interactive terminal is connected to either a Model 2236MXD Terminal Processor or a Model 22C32 Triple Controller when configured with a 2200MVP or 2200VP Central Processing Unit (CPU). These devices control I/O operations between the CPU and the terminals, and buffer data entered from or transferred to the interactive terminal. The Model 2236MXD can be used on the 2200MVP or 2200LVP. The Model 22C32 Triple Controller supports a single terminal and can be used on the 2200VP, or 2200MVP CPU.

Model 2236D-type terminals can be attached locally to the 2200MVP CPU at distances up to 2,000 feet (606.1 meters), or remotely via modems and telephone lines.

- Local Connection — For distances up to 25 feet (7.6 meters), transmission rates of 19.2K bits per second (bps) are available with direct connection using a Wang-supplied cable. A local connection is the standard configuration.

- Extended-Local Connection — For distances from 25 feet (7.6 meters) to 2,000 feet (606.1 meters), optional Wang-supplied cables provide direct extended-local connection with transmission rates of 19.2K bps. (Refer to Appendix A for a list of available cable lengths.)

The 22C32 Triple Controller has a fixed communication rate of 19,200 bps. A terminal attached to that controller must be local (i.e., direct connections up to 2,000 feet from the CPU). However, with the 2236MXD Terminal Processor, transmission rates ranging from a minimum of 300 to a maximum of 19,200 bps may be selected. (Possible transmission rates include 300, 600, 1200, 2400, 4800, 9600, and 19.2K bps, where 19.2K equals about 1,750 characters per second.) Both the Model 2236MXD and the terminal connected to it must be set at the same data transmission rate. The procedure for setting the transmission rate is discussed in Appendix F.

J.2 REMOTE CONNECTION USING MODEMS

Remote use of 2236D-type interactive terminals is also possible using the built-in telecommunications capabilities of the 2236MXD Terminal Processor and the terminal itself. With the addition of the proper modems, the 2236MXD can communicate with 2236D-type terminals over unlimited distances. Speeds ranging from 300 to 9600 bps can be attained by using readily available modems and communications lines supplied by various common carriers and modem vendors. This equipment is not available from Wang Laboratories, Inc.
When the 2236MXD Terminal Processor is used to transfer information from the CPU to the terminals over common carrier lines, the digital signals of the processor must be translated into corresponding analog signals at the sending end and returned to digital form at the receiving end. The same transformation must be performed on information transferred from the terminal to the CPU. Data is converted from one form to another by using modems, devices which first modulate the digital signals and then demodulate the resultant analog signals.

Two modems are needed for each remotely used terminal. One modem must be located at the site of the 2236MXD Terminal Processor, and the other modem must be located at the site of the 2236D-type interactive terminal. Both modems must be either the same model or, if they are different models, compatible, in order to permit the remote terminal setup to function. In particular, the speed, type of communication, and number of bits expected to be received must be identical for both modems.

The type of modem used and the speed of transmission depend largely on the distance which the signals will travel between the modems. The following are possible remote connections.

- **Short-Haul Connection** — For distances from 2,000 feet (606.1 meters) to 5 miles (8 kilometers), short-haul modems are used with either private or leased lines. A maximum speed of 9600 bps can be maintained. Equipment designed for long-haul applications may also be used to establish a short-haul connection.

- **Long-Haul Connection** — For distances greater than 5 miles (8 kilometers), either switched or leased lines can be used for signal transmission. Depending on the type of line used, obtainable speeds range from 1200 to 9600 bps.

Switched lines are accessed through the common carrier’s switching system by telephone dialing. The speed on switched lines is usually limited to 1200 bps because the switching apparatus may introduce noise on the line. A leased line presents a faster, but more costly, alternative to a switched line.

Unlike switched lines, a leased line is a communications line leased from a common carrier in the area for the exclusive use of the customer. When a leased line is used to transmit signals, the line is run directly from the CPU to the terminal location and no switching occurs. Speed on a leased line may be as high as 9600 bps; however, the customer must determine whether the increase in transmission speed justifies the additional expense of a leased line. Information about leased lines and their cost should be obtained from the common carrier in the customer’s area.

Communication between the Model 2236MXD Terminal Processor and the 2236D-type interactive terminal is asynchronous serial. Data is sent one bit at a time, with each character framed by a number of control bits. The 2236MXD Terminal Processor and the 2236D-type terminal send eleven bits for each character transmitted: one start bit, followed by eight data bits, followed by a parity bit, and ending with one stop bit. The start bit indicates the beginning of the character to be transmitted. The following eight bits represent the character which has been sent, and the parity bit serves as an error-checking technique. The 2200MVP utilizes odd parity, i.e., the parity bit is set to logical one or zero so that the total number of logical one bits in the character plus the parity bit is always odd. When either the 2236 MXD Terminal Processor or the 2236D-type terminal receives a character, a
count is made to ensure that the number of logical one bits is odd. If the number of logical one bits is even, the error is recognized and the terminal signals this error by displaying a # on the CRT screen or terminal printer and then sounding the audio alarm. (A parity error discovered by the 2236MXD Terminal Processor results in conversion of the offending character to a #, which is then sent to the terminal.) The stop bit indicates the end of the transmitted character.

In addition to being asynchronous, communication between the 2236MXD Terminal Processor and the remote terminal is full-duplex, enabling data to travel simultaneously from the 2236MXD Terminal Processor to the terminal and from the terminal to the 2236MXD Terminal Processor. Therefore, modems utilized in this system must be full-duplex and capable of asynchronous transmission.

Asynchronous modems may be either hardwired or acoustically coupled to communications lines. (Refer to Figure J-1.) Hardwired modems are attached directly to the communications line. A hardwired modem may be attached to a telephone used for dialing a switched line, or it may be the sole device attached to a leased line. When a switched line is used, the modem at the CPU site should be equipped with automatic answer and automatic disconnect capabilities. These features allow communication with remote terminals to be automatically established when the remote station dials the central site, and automatically terminated when the remote station hangs up. The acoustic coupler is a free-standing modem that is attached to the communications line by an ordinary telephone. The telephone handset is inserted into cups on the acoustic coupler. The telephone picks up the analog signals generated by the modem as audible tones and transmits these tones to the other modem. When audible signals return to the telephone, the acoustic coupler picks them up and converts the audible signals to digital signals. Acoustic couplers are used only with switched lines; hardwired modems can be used with either switched or unswitched lines.

![Diagram of modem and acoustic coupler connections](attachment:diagram.png)

**Figure J-1. Hookup of Hardwired Modem and Acoustic Coupler**

Since transmission is occurring in two directions simultaneously, the two modems must transmit at slightly different tones to prevent confusion of signals. Therefore, one modem is considered to be the originating modem, and the other is the answering modem; each transmits at a different pitch. Although each modem should be able to transmit as either an originating or an answering modem, only one modem of each type is required for the remote terminal setup to function. Typically, the originating modem is located at the remote site and the answering modem at the central site. This setup allows the remote terminal to initiate the communication. It is possible, however, to set modems up in the opposite manner.
To summarize, the modems used must be:

- Asynchronous.
- Full-duplex.
- The same or a compatible model.
- Capable of transmitting at least 11 bits per character: one start bit, eight data bits, one parity bit, and at least one stop bit.
- Capable of the desired transmission speed.
- Suitable for the type of line being used.
- Set to the same transmission speed. (The processor and terminal must be able to operate at this speed.)

Failure to ensure speed compatibility among all components in a communications link is one of the most common sources of error encountered in telecommunications.

**J.3 LINE AND MODEM COMBINATIONS**

There are four recommended combinations of lines and modems.

1. Switched line, with hardwired modems at both sites; 1200 bps maximum. This combination is the most common option. (Refer to Figure J-2.)

2. Switched line, with an acoustic coupler at the remote site and a hardwired modem at the central site; 1200 bps maximum. (Refer to Figure J-3.)

3. Leased line, with hardwired modems at both sites; 9600 bps maximum. (Refer to Figure J-4.)

4. Short-haul line [private cable or leased line, up to 5 miles (8 kilometers) in distance], using short-haul modems at both the remote and central sites; 9600 bps maximum. (Refer to Figure J-5.)

![Figure J-2. Switched Line and Hardwired Modems](image-url)
The 2236D-type terminal has been designed to allow communication at 1200 bps over switched lines between most points in the continental United States. Over extremely long distances, the protocol used between the terminal and the controller fails because of communication channel propagation delays. Therefore, there are some restrictions imposed on the maximum distance a 2236D-type terminal may be located from the controller. In general, the common carrier should be consulted for detailed propagation delay specifications before attempting communication via international phone lines, especially satellite channels. Similar restrictions apply to the use of digital data services, such as packet switching networks and line multiplexing devices (e.g., statistical multiplexers).
It is not necessary for the 2236D-type terminal, or the printer attached to it, to keep up with the data stream coming in over the communication line. If the CRT or printer falls behind such that it is beyond the capability of the terminal to buffer the data, the terminal sends a Stop Sending command character to the processor. Over extremely long communications lines, the time it takes for the Stop command to reach the processor becomes significant. Therefore, although the terminal has sent a Stop Sending command, there is some delay before the processor actually receives the command character. Because of the delay, the processor receives the Stop Sending command after it has transmitted characters to the terminal. This delay, between the cause of an event (the need to send a Stop Sending command) and the effect of an event (terminal processor awaits command) may be defined as hysteresis. The non-Wang supplied communication equipment (modems, communication channel, etc.) may not impose more than 64 characters of hysteresis round trip between the terminal and the processor, if terminal buffer overruns are to be prevented. The 64 characters may be the result of time delays and/or digital buffering. (If data is lost over a long communication line, try lowering the data rate.) The most common situation is the case in which a time delay is caused by a long communication line. In such a case, it is useful to express the allowable network hysteresis in terms of time.

\[
\text{Time in seconds} = \frac{(64 \text{ characters}) \times (11 \text{ bits per character})}{(\text{Data rate in bits per second})}
\]

At 1200 bps, 64 characters times 11 bits per character works out to about a one-half second keystroke echoing delay. However, it is not wise to push the 2236D-type Interactive Terminal to its 64-character limit, as the keystroke echoing time begins to deteriorate.

### J.4 SETTING UP THE DATA LINK

Once the transmission speed, type of line, and location of the remote terminal have been selected, setup of the remote terminal system may begin. A modem must be selected and either purchased, rented, or leased from a vendor. (A list of vendors is provided at the end of this chapter for customer convenience.) Connecting the modems to the communications line is the responsibility of the modem vendor or the common carrier providing the line; it is not the responsibility of Wang Laboratories, Inc.

When the modems are installed, the customer must contact a Wang service representative, who will then connect the 2236MXD Terminal Processor and the 2236D-type terminal to the modems. The connection must be made using an RS-232-C compatible cable and not the standard processor/terminal connecting cable. The RS-232-C cable is available in the following lengths.

- 12 feet (3.7 meters, part number 120-2227-12)
- 25 feet (7.6 meters, part number 220-0219)
- 50 feet (15.2 meters, part number 220-0220)

Two cables are required for each remote terminal; one cable is connected directly between a port on the 2236MXD Terminal Processor and the modem at the central site, and the second cable is connected between the 2236D-type terminal and the modem at the remote site. (Refer to Figure 4-6.) No special communications controller or emulation software is necessary to operate the remote terminal, since all appropriate electronics are built into the processor and terminal. The terminal connected to Port 1 of the primary 2236MXD Terminal Processor is designated as Terminal 1. Do not use Port 1 on the 2236MXD Terminal Processor to support a remote terminal. Terminal 1 should reside in the same area as the CPU because this terminal acts as the system console for Master Initialization when the system is turned on, and is responsible for reporting and correcting system errors.
J.5 ESTABLISHING COMMUNICATION

Once the installation process is complete, the modems are set for asynchronous, full-duplex operation, and all components are set to the same transmission rate, the remote terminal setup is complete. The next step is to establish communication between the remote terminals and the CPU. Once communication is established, the remote terminal behaves exactly as if it were a locally connected 2236D-type terminal.

One common setup involves an acoustic coupler at the remote site, a switched line, and a hardwired modem at the CPU site. To establish communication, the operator at the terminal site turns on the power to all equipment and dials the number of the line to which the 2236MXD Terminal Processor's modem is attached. If the modem attached to the Model 2236MXD Terminal Processor is not an automatic answering model, an operator at the central site must answer the telephone and ready the central site by pressing the telephone button which sets that end of the link to the Data mode. Pressing this button allows the modem to begin transmission. If the modem has an automatic answer feature, the line is "picked up" without operator intervention. In either case, the terminal operator then hears a high-pitched tone on the telephone. The telephone handset should then be placed in the cups of the acoustic coupler. The orientation of the telephone handset must conform to the explanation noted on the modem itself or in the accompanying instructions. An indicator on the acoustic coupler illuminates when a proper connection has been made. The CRT screen should display the READY (BASIC-2) message at this point. If no message appears, RESET should be pressed; the message will then be displayed.

If hardwired modems are used at both ends of a switched communications link, the procedure for establishing communication between the remote terminals and the CPU resembles the procedure used when an acoustic coupler is located at the remote site. When hardwired modems are located at both sites, however, the operator at the terminal site presses the Talk button before dialing the number, listens for the high-pitched tone, and then presses the button on the telephone for the Data mode to establish communication. An indicator on the modem illuminates when the proper connection has been made. Again, if the modem at the CPU site does not have an automatic answer feature, operator intervention at that site is necessary to establish the link.

In the case of a leased line, the modems are always active and the line is always open. No special procedures are necessary to establish a communications link.
The vendor or common carrier supplying the modem should establish all modem switch settings at the time of installation. Transmission rate switches on the 2236D-type interactive terminal and 2236MXD Terminal Processor should be set by a Wang service representative at the time of installation. It should not be necessary to set any switches when the communications link is established.

If a link cannot be established, the following procedures should be observed.

1. Ensure that all power switches at both the remote and central sites are set to ON (including power to modems). Check that the 2200MVP system is operational and ensure that its configuration includes at least one partition assigned to the 2236MXD Terminal Processor port corresponding to the remote terminal. Check that all connections are intact and that the modem at the central site is plugged into the correct port on the 2236MXD Terminal Processor.

2. Check that the transmission speeds selected for both modems, the 2236MXD Terminal Processor port to which the central modem is attached, and the 2236D-type terminal are in agreement.

3. Examine the indicator lamp on each modem to ensure that a connection was made. If the indicator is not illuminated, follow the normal procedure for establishing the telecommunications link. If this approach fails, continue with Procedure 4.

4. The 2236D-type terminal depends on the 2236MXD Terminal Processor for character echo. Each keyed character is transmitted to the 2236MXD Terminal Processor, which then sends the same character back to the CRT for display. No screen output will appear on a remote CRT if data is not being sent back to the terminal from the 2236MXD Terminal Processor. It is therefore useful to isolate the terminal from the 2236MXD Terminal Processor to determine if the terminal is functioning properly. Most modems have test settings called local test or loop back. These settings allow the terminal to send characters from the keyboard to the modem, which then transmits these characters directly to the CRT. (These tests may be performed by the customer or the modem supplier.) If these tests generate screen output, the line itself or the equipment at the central site may be the source of the problem. If tests at the central site indicate no local trouble, call the common carrier who supplied the communications line. (Procedure 5 outlines tests to be performed at the central site.)

If no echo can be observed at either the remote or the central site after performing this procedure, the modem supplier should be contacted and the modems tested. The common carrier can test modem operation from a central site and a field visit is not required. If the modems are operational, contact the common carrier and determine whether the communications line is functioning properly.

5. If the remote site is free from problems, both the modem and the 2236MXD Terminal Processor at the central site should be checked. The modem may be checked as in Procedure 4, using a local terminal and the RS-232-C compatible cable. The 2236MXD Terminal Processor may be tested by configuring the system for four-terminal, four-partition operation and then, using standard terminal cable, attaching a local terminal to each port in succession.
If the modem test fails, contact the modem vendor. If the 2236MXD Terminal Processor does not function properly, contact a Wang service representative.

6. If all other components are functioning properly, yet no link can be established, contact a Wang service representative.

### J.6 MODEM SUPPLIERS

Modems can be obtained from several sources and can be purchased, rented, or leased. The Bell Telephone Company is the largest supplier of modems in the United States. Although not a supplier of short-haul modems, Bell Telephone does supply a number of modems for long-haul applications. The local business office can be contacted for information.

Other manufacturers and suppliers can provide modems for 2200MVP remote terminal operations. The asynchronous modems at both ends of the remote terminal communications link must be RS-232-C/CCITT V.24 compatible and also compatible with each other. Furthermore, the modems must be capable of transmitting data with 11 bits per character (1 start bit, 8 data bits, 1 parity bit, and 1 stop bit).
APPENDIX K
2200MVP SYSTEM UTILITIES

K.1 ACCESSING THE SYSTEM UTILITIES MENU

Included with the 2200MVP system software are certain programs of general usefulness known as *utilities*. These utilities are intended to simplify such commonly-performed system tasks as backing up a hard disk onto diskettes and moving files.

Utilities can be accessed through a utilities menu which is available through the system platter. The following two commands will display this menu.

1. SELECT DISK xxx (Return)
   The device address of the disk on which the system utilities reside is xxx.

2. LOAD RUN (Return)

Utilities which require operator-entered information will display a series of prompts requesting this information. In all cases, type in the necessary response and press RETURN; the utility will then request additional information or perform the required procedure.

K.2 THE SYSTEM UTILITIES MENU

Partition Generator (@GENPART)

This utility creates, saves, and executes system configurations which divide the 2200 resources among the system users. This program is stepped through in Section 3.2 of this manual.

Partition Status (@PSTAT)

This program displays a table indicating the current status of each partition in the current configuration. The table consists of the following information: the bank in which the partition resides; the size of the partition; the partition number; what terminal is currently attached to the partition; whether the partition is programmable; whether the partition has been defined as global and if so, what name it has been assigned; if a partition message has been set using the $PART statement; the number of the partition to which the program, data, and global operator pointers currently point; where the last error was encountered; and the device number of the last I/O operation. (Refer to $PSTAT in the BASIC-2 Language Reference Manual for additional information on partition status.)
Move System Files (@MOVE)

The purpose of this utility is to allow for the installation and updating of system files. It does this by moving specified system files (files beginning with the @ character) from one disk platter to another. The utility moves one file at a time. The Move System Files utility can be used to update system files by overwriting existing system files. The operator is notified if a file existing on the destination platter has the same name as the file the operator intends to copy and the utility requests permission to overwrite.

Format Disk Platter (@FORMAT)

This program formats software formattable disk platters, such as 2260C, 2260BC, 2280 platters, dual-sided double-density diskettes and 2200MVP fixed disks. Running this utility produces the same results as executing a $FORMAT command. (Refer to the appropriate disk reference manual for detailed formatting information.)

2273 Vertical Format Control (@2273VFU)

This utility allows the user to define and edit the vertical format of the Model 2273 Band Printer’s Direct Access Vertical Format Unit (DAVFU) without the difficulty of programming long code sequences. The user can create, edit, test, and save format data on disk for later loading into the DAVFU. Each time the utility is used, the user indicates whether he or she wants to load a previously-created format file or create a new one.

In creating a new vertical format, the user responds to operator prompts and specifies the number of lines per page, the number of lines per inch, and the location of the bottom of form. Once this information is supplied, an N x 12 grid appears on the CRT screen: N representing the specified number of lines and 12 being the number of channels of the DAVFU. The operator can edit the format by entering tabs indicating top-of-form in Channel 1 of Line 1 and bottom-of-form in Channels 1 and 2 after the last line to be printed. Tabs may be set in the channels of other lines to indicate vertical stops.

Backup Platter (@BACKUP)

The Backup Platter utility provides the ability to copy the contents of a single disk platter to another platter or to a series of smaller platters. The source and destination platter may be from any of the several types of disk drives used on the 2200MVP. The primary purpose of this utility is to allow the 2-, 4-, or 8-megabyte fixed disks on the 2200MVP to be backed up onto several 1-megabyte diskette platters. This utility moves the entire contents of the source platter, including the catalog index if one is present.

This utility overwrites any information already contained on the platter(s) specified for output. Additionally, the backup platter(s) created by this utility stores file names in a data file instead of a copied catalog index, and thus cannot be used for direct file access. To retrieve the contents of the backup platter(s), the Retrieve Platter utility must be used.
Retrieve Platter (@RECOVER)

This utility is the complementary utility to the Backup Platter utility; it retrieves the contents of the platters produced by the Backup Platter utility and writes them onto another platter. The Recover Platter utility provides three options for recovering data.

1. Recover the entire content of the backup platter(s). If an exact copy of the original source platter is required, or if the source was an uncataloged platter, this option must be used.

2. Recover all the active files on the backup platter(s). This option provides an efficient means of removing all scratched files from the backup platter(s).

3. Recover select files from the backup platter(s). This option provides for the recovery of individual files from the backup platter. The files that are recovered may be added to a cataloged disk which need not be identical to the original source platter. This option also provides the ability to enlarge the size of the file, if desired.

The Recover Platter utility can only be used to retrieve information from a platter created by the Backup Platter utility. Other, more general file movement can be achieved by using the Move File utility.

Move File (@MOVEFIL)

The Move File utility provides a general file move capability. Specified files are moved from one platter to another; if necessary, a file can span more than one output platter. This utility can create a new file, change the new file size for new output files, rename a file, and overwrite an existing file.

Customer Comment Form

Help Us Help You...

We’ve worked hard to make this document useful, readable, and technically accurate. Did we succeed? Only you can tell us! Your comments and suggestions will help us improve our technical communications. Please take a few minutes to let us know how you feel.

How did you receive this publication?

☐ Support or Sales Rep
☐ Wang Supplies Division
☐ From another user
☐ Enclosed with equipment

How did you use this Publication?

☐ Introduction to the subject
☐ Classroom text (student)
☐ Classroom text (teacher)
☐ Self-study text

☐ Aid to advanced knowledge
☐ Guide to operating instructions
☐ As a reference manual
☐ Other

Please rate the quality of this publication in each of the following areas.

EXCELLENT       GOOD       FAIR       POOR       VERY POOR

Technical Accuracy — Does the system work the way the manual says it does?

Readability — Is the manual easy to read and understand?

Clarity — Are the instructions easy to follow?

Examples — Were they helpful, realistic? Were there enough of them?

Organization — Was it logical? Was it easy to find what you needed to know?

Illustrations — Were they clear and useful?

Physical Attractiveness — What did you think of the printing, binding, etc?

 Were there any terms or concepts that were not defined properly?  ☐ Y ☐ N If so, what were they?

After reading this document do you feel that you will be able to operate the equipment/software? ☐ Yes ☐ No ☐ Yes, with practice

What errors or faults did you find in the manual? (Please include page numbers)

Ordering Instructions

1. If you have purchased supplies from Wang before, and
   know your Customer Number, please write it here.
2. Provide an appropriate Billing Address and Shipping Address.
3. Please provide a phone number and name, should it be
   necessary for WANG to contact you about your order.
4. Your purchase order number and date.
5. Show whether order is taxable or not.
6. If tax exempt, please provide your exemption number.
7. If you wish credit for this order to be given to a WANG
   salesperson, please complete.
8. Show part numbers, description and quantity for each
   product ordered.
9. Pricing and subtotal can be completed at your
   option; Wang will add tax on your invoice.
10. Signature of authorized buyer and date.

Wang Supplies Division Terms and Conditions

1. TAXES — Prices are exclusive of all sales, use, and like
   taxes.
2. DELIVERY — Delivery will be F.O.B. Wang's plant.
   Customer will be billed for freight charges, and unless
   customer specifies otherwise, all shipments will go best
   way surface as determined by Wang. Wang shall not
   assume any liability in connection with the shipment nor
   shall the carrier be construed to be an agent of Wang.
   If the customer requests that Wang arrange for insurance
   the customer will be billed for the insurance charges.
3. PAYMENT — Terms are net 30 days from date of invoice.
   Unless otherwise stated by customer, partial shipments will
   generate partial invoices.
4. PRICES — The prices shown are subject to change without
   notice. Individual document prices may be found in the
   Corporate Publications Literature Catalog (700-5294)
5. LIMITATION OF LIABILITY — In no event shall Wang be liable
   for loss of data or for special, incidental or consequential
   damages in connection with or arising out of the use of or
   information contained in any manuals or documentation
   furnished hereunder.
